Constitution of Xylan Previous work on the structure of the polysaccharide xylan revealed that the substance was composed of chains of xylopyranose units linked through the 1–4 positions of the pentose molecule The glycosidic linkages were known to be β in type, and in many ways xylan presented close structural analogies with cellulose More recent investigations by W N Haworth, E L Hirst and E Oliver (*J Chem Soc*, 1917, 1934) show that xylan prepared from esparto celluloses of different origin is possibly more closely related to the plant gums than to normal cellulose It contains, in addition to the xylopyranose residues, a fixed and constant proportion of combined l arabinose in the furanose form This l-arabofuranose unit is retained during methylation and the methylated xylan gives on hydrolysis 90 per cent of 2 3 dimethyl xylose and about 6 per cent of 2 · 3 5 trimethyl l-arabofuranose The last product shows that the arabinose residue must be present in the furanose condition in xylan and that it forms a terminal group attached to a chain of consecutive xylopyranose residues—the first occasion on which the natural occurrence of arabofuranose has been observed Xylan is non-reducing, and previous experiments by Schmidt in favour of a terminal carboxyl group could not be confirmed. Trimethyl xylose has not been detected in the cleavage products of methylated xylan, and it seems evident that the trimethyl arabofuranose takes the place of this as a terminal group in what is otherwise a series of xylopyranose units Alternative structures which are possible in the present stage of the investigation are considered

The Spectroscopic Binary ζ Aurigae Work performed at Cambridge at the recent eclipse of the variable ζ Aurigae is described in the November *Monthly Notices R A S* This spectroscopic binary is also an eclipsing variable and consists of a K type super giant and a B star, and has an especial interest since it is the first accurately to give the dimensions and mass of a red supergiant from observations alone The Cambridge observations consisted of an accurate measurement of the magnitude difference between the normal and eclipsed system, made by Dr. W M Smart with a photo-electric photometer. The difference was found to be 2·281 m, with the very small probable error of 0·004 m At the same time, spectroscopic observations were made at the Solar Physics Observatory These are described by Dr A. Beer. A remarkable feature is the appearance of the Ca^+ lines in absorption in the violet spectrum of the B star when this star emerges from the eclipse. Naturally, these lines are absent from the normal B spectrum, which is readily distinguished from the K spectrum in the violet by its greater intensity The appearance of the Ca^+ lines is due to the passage of the light from the B star through an extensive Ca^+ chromosphere or envelope carried by the red star As the B star moves clear of the eclipsed position, these Ca^+ lines decrease in intensity. The distance between the two stars is about 10^{19} km, and their diameters 335 and $2\frac{1}{2}$ times that of the sun, for the red supergiant and B star respectively.

Twenty-second Session of the Indian Science Congress

THE twenty-second session of the Indian Science Congress was held at Calcutta on January 2–8. The session was memorable for the foundation of the National Institute of Sciences of India, which it is intended shall perform for India some of those functions which the Royal Society discharges with regard to science in the United Kingdom. The foundation of this Institute forms a land-mark in the organisation of scientific research in India. The inauguration ceremony of the National Institute was performed on January 7 by His Excellency Sir John Anderson, Governor of Bengal, when Dr. L. L. Fermor, president, delivered his presidential address.

His Excellency Lord Willingdon, Viceroy and Governor-General of India, opened the session on January 2. In his speech, Lord Willingdon referred with satisfaction to his being the first Viceroy to be present at its meetings, and mentioned briefly the importance of the contribution to Indian science being made by Government through scientific services and scientific departments, and through the agency of bodies like the Imperial Council of Agricultural Research and the Indian Research Fund Association. After mentioning the munificent endowments for scientific research created by men like the late Sir Jamshetji Tata, the late Sir Tarak Nath Palit and the late Sir Rash Bihari Ghosh, he mentioned specially the growing contact between scientific research and the practical demands and requirements of industry, of which the assistance given by the Burma Oil Company to the foundation of the College of Engineering at Rangoon, and the recent donation of Messrs. Steel Brothers for research in oil technology at Lahore, are examples. In concluding, he referred to the necessity for scientific workers to organise themselves so as to ensure the maximum of achievement that is possible with the resources available.

In his presidential address, Dr. J. H. Hutton referred briefly to the work of the Academy Committee appointed at the Bombay session and recommended the scheme for the foundation of a National Institution of Sciences of India for adoption by the Congress. He then referred to the vast field available in India for the organised efforts of science, and cited rural economy, food reform and town planning as matters in which science may and should be utilised and directed for the benefit of the community. Speaking of the vast field India offers to anthropologists, containing as it were a veritable museum of living physical types, of social organisations, cultures and religious beliefs, he pointed out that the question of race in India requires very careful and detailed examination by trained anthropologists. He directed attention to the numerous sites of archæological interest awaiting excavation and to the great need for systematic linguistic research in southern India. The necessity of studying the symbolism of dreams, folk-lore proper and religious beliefs and practices was emphasised and an appeal was made to concentrate more on the organised collection of facts than on their interpretation.

In his presidential address to the Section of Agriculture, Dr. F. J. F. Shaw laid stress on the necessity and importance of systematic breeding work for resistance to disease. In this connexion he mentioned the production at Pusa of new types of Rahar (pigeon pea—*Cajanus indicus*) resistant to the wilt disease caused by *Fusarium*. He also mentioned that a comprehensive scheme for breeding rust-resisting types of wheat has recently been undertaken by the Imperial Agricultural Department, from which it is hoped fruitful results will be obtained. After referring to breeding work done on linseed, potato and sugar-cane in India, he pointed to the necessity of a cytological study of these crops. He hoped for co-operation in this sphere from the universities of India.

At a joint meeting of the Sections of Agriculture, Mathematics and Physics, Chemistry, Botany, Geology and Zoology, it was decided to start an Indian Society of Soil Science.

The presidential address by Prof. N. R. Sen to the Section of Mathematics and Physics was a general review of the development of theoretical physics from the early stage of classical mechanics to the present state of quantum mechanics, laying special stress on the difficulties of the existing theory. The viewpoints of the two rival schools of thought, namely, of a continuous field theory being able to describe correctly the entire scheme of Nature, or of discontinuous quantum processes ultimately finding a solution to the problem of matter and radiation, were analysed and discussed.

Among the papers read at the meetings the following may be mentioned: (1) atomic arrangements in anthraquinone crystals, by Dr. K. Banerjee, (2) aerial waves produced by meteorites, by Dr. S. K. Banerjee, (3) meteorological papers on nocturnal cooling of the atmosphere by radiation, by Dr. K. R. Ramanathan and Mr. Ramdas, (4) Heilbronn's class-number, by S. Chowla, (5) some boundary problems in non-linear parabolic equations, by R. Siddiqi, and (6) two hydrodynamical papers, by N. Bose and S. Sen Gupta.

In his address to the Chemistry Section, Dr. A. C. Sarkar gave a review of recent work on high coal-tar hydrocarbons, especially acenaphthene, fluorene and phenanthrene. Symposia were held on chemical aspects of light absorption and cellulose chemistry.

The presidential address of Diwan Anand Kumar to the Zoology Section dealt with the spicules and classification of Tetraxonida, an order of non-calcareous sponges. Apart from the papers read, the Section discussed at its meetings the question of "Standardisation of the Courses in Zoology for the University Examinations" and at a joint meeting of the Botany and Zoology Sections the "Teaching of Elementary Biology in Secondary Schools in India". The Section adopted a resolution stressing the need for the establishment of a station for marine and estuarine biology in Bengal. A committee was also appointed to organise a Zoological Society for India.

Prof. J. H. Mitter, in his presidential address to the Botany Section, dealt exhaustively with mycological and plant pathological research in India. He laid stress on the need of co-operation between universities and the plant pathologist, who has not always much time at his disposal to carry out the purely scientific work on the life-history of the pathogen. He further pointed out the desirability of establishing a bureau of stock cultures of fungi and the publication of an up-to-date textbook on mycology for India.

The problem of cereal rusts in India was discussed at a joint meeting of the Botany and Agriculture

Sections. Dr. K. C Mehta, Dr U N Pal, Dr F J F Shaw, Mr P. K. De and Dr. B B Mundkur took part in the discussion

The presidential address to the Geology Section by Dr M S Krishnan dealt with the classification of the Dharwar system of Pre-Cambrian rocks. A three-fold division was suggested in which the lowest consists of a metamorphosed complex, while the middle division is characterised by manganese ores (gondite type) and marbles, and the upper one by banded ironstones. The origin of some of the types of sediments in this system was discussed in the latter part of the address

In addition to the papers which were contributed to this Section, there was a symposium on the Bihar earthquake of 1934, jointly with the Physics Section, in which Drs. A C Banerji, S. K Banerjee, C W B Normand and S C Roy and Messrs D N Wadia and W D. West took part S K Banerjee touched upon some general facts and exhibited a model of a seismograph of his own design suited for recording severe shocks near the focal region, A C Banerji discussed the inter-relationship of the cooling of the crust and the distribution of radioactive material in the earth, and also the influence of the tidal attraction of the sun and the moon in precipitating an earthquake in an unstable crust Roy illustrated his remarks with actual seismograms and the various phases found therein According to him the focal depth of this earthquake was about 13 5 km, and the speed of one phase coincided with that in dunite. Normand emphasised the necessity for more seismographs and especially damped instruments in the Indo-Gangetic valley adjoining the Himalayan seismic belt Wadia dealt with the geological aspects and on the possibility of the existence of fractures parallel to the 'Main Boundary Fault' underneath the Ganges valley in Bihar, while West from geodetic considerations thought that the earthquake might have been produced by the conversion of the rocks of the eclogite and dunite shell into those of less density.

Major K R K Iyengar devoted his presidential address to the Section of Medical and Veterinary Research to the consideration of the problem of rabies in India He pointed out that all attempts to cultivate artificially the organism causing it having failed, it is not possible to improve upon the somewhat crude methods employed at present to prepare the serum and to devise more efficacious means of prophylactic treatment Certain improvements in the technique of preparing serum adopted during the previous year at Coonoor were described It was further pointed out that although a number of institutes for anti rabies treatment have been established in India, no preventive measures are being taken to deal with the disease at its source Referring to the example of Germany, Australia and the British Isles where rabies has been eradicated by strictly controlling dogs and their movements, Major Iyengar pressed for co-operative efforts for the destruction of stray ownerless dogs, and for the compulsory registration and licensing of dogs in all municipalities and district boards He advocated destruction of jackals as well in rural areas Quarantine methods against imported dogs, in his opinion, would not be effective unless the local dog population is properly controlled He recommended that anti-rabies treatment should be decentralised to the utmost extent possible, so that persons bitten by dogs could have treatment near their homes

A symposium on vitamins was held at a joint meeting of the Sections of Chemistry and Medical and Veterinary Research

Dr G. S Ghurye took "Anthropology and our Educational System" as the theme of his address to the Anthropology Section If anthropology is to serve as a guide to better social conditions, a study of the social and cultural history of the various races of mankind, primitive as well as advanced, is very necessary Such a study would help in suggesting solutions to many pressing social problems: It was therefore suggested that anthropology should be included as a subject in all courses of study prescribed for students wishing to take up public life in one form or other as their career.

The Section adopted a resolution to start an Anthropological Society for India, if possible by enlarging the scope of the Bombay Anthropological Society

In his address to the Psychology Section, Dr S C Mitra dealt with the relation of psychology to problems of life After pointing out the various ways in which a knowledge of psychology can be utilised to solve social problems, he pressed for the establishment of an Institute of Applied Psychology

S P AGHARKAR.

Underground Water Supplies

ALTHOUGH the title of his paper, read before the Royal Society of Arts on February 20, was "Water Supplies from Underground Sources", Lieut -Col. J. D Restler gave it a rather wider scope by including some preliminary notice of water supplies in general He pointed out that the problem of water supply is very different from that of the supply of gas and electricity, because gas and electricity can be manufactured for all practical purposes at any point where it is desired to do so, and electricity can be transmitted in bulk over long distances with comparative ease and relatively high efficiency, whereas in the case of water, serious engineering difficulties arise if large quantities are to be delivered over long distances. The capital cost becomes very heavy and the efficiency, due to pipe friction and other causes, is exceedingly low.

Dealing more particularly with the subject of subterranean supplies, Col. Restler described the conditions under which they have to be obtained In sinking a well, or boring, in many localities, it is quite usual to pass through a large number of strata yielding water of an entirely different character, separated in some cases by comparatively few feet The classes of water met with vary to such an extent that some may be so soft as to attack lead pipes, and others so hard as to be entirely unsuitable for steam raising or domestic purposes Others again, right in the centre of England, may be quite salt As a general principle, if underground water of suitable quality can be found in sufficient quantity at a convenient depth and within a reasonable distance of the locality where it is required, such a source, from a water undertaking point of view, has great advantages over a surface or river source Underground sources of supply are less liable to

contamination, assuming that there is a sufficient covering of impervious strata and that the outcrop lies in an area where only pure rain water is collected

The engineering works required for obtaining water from water-bearing strata may be divided into three sections, the first being small borings, such as those required for the supply of small quantities to country houses, medium size factories, etc, the second section would comprise large borings, such as those required for public water supply undertakings or large manufacturing works, and the third section would consist of large wells, with headings or galleries, such as those required for the supply of large towns and cities Borings under the first category would be capable of delivering water at the rate of about 100,000 gallons in twenty-four hours, those in the second category at the rate of about two million gallons in twenty-four hours, and those in the third category at a rate exceeding five million gallons in twenty-four hours The first and second classes have many points in common, the principal difference being that the plants and apparatus required in the second case are considerably larger and heavier The paper then went on to describe the procedure of making the borings and sinking the lining tubes

In the course of his paper, Col Restler mentioned that water derived from an underground source is, in very cold weather, many degrees higher in temperature than water derived from a river source, and that it is quite noticeable that the former does not freeze in mains or service pipes so soon as river water This is a point of practical importance, because when very cold water is being transmitted through mains, it frequently produces a local contraction in the metal and causes cast iron pipes to fracture

Post-Glacial Research in Ireland

IT has been evident for many years that a large number of the special problems of plant and animal distribution in Ireland could only be solved if it were possible to obtain trustworthy evidence as to the major post-glacial changes in the Irish fauna and flora Accordingly a committee was formed in 1933, with the object of promoting detailed investigations of representative glacial and post-glacial deposits and, particularly, of enlisting the method of pollen analysis in the detailed study of the problem The work and aims of the committee up to the end of 1934 are summarised by various authors in the November number of the *Irish Naturalist* (5, 125, 1934). Active field work was commenced in 1934, so that full details of the results are not yet available The particular feature of the work was, however, that the sites examined were chosen because they included definite and representative archæological horizons in various parts of the country

An outline of the broad results of the pollen analyses of peats is given by Prof Knud Jessen, and this indicates the main features of the work attempted. From results on the deeper bogs examined, the tentative suggestion is made that there was an increase in moisture in the later part of the Bronze Age, which occasioned wide-spread replacement of forest by peat bog. If, as is possible, this change corresponds in time with the sub-boreal to sub-Atlantic climatic change so well known on the Continent, the late Bronze Age in Ireland should synchronise with the beginning of the Iron Age (Halstatt period) in Europe. Before this transition, Ireland was forest clad to the western coasts and high up the mountains. Since then, forests have disappeared from western Ireland

Investigations carried out in Northern Ireland were devised to secure, if possible, chronological comparisons between the raised beaches and the development of inland bogs containing Stone Age culture layers The results will be awaited with interest, as will those from the Lough Neagh area, where the discovery of fossil *Naias flexilis* fruits may throw light on the origin of the American element in the Irish flora The late glacial deposits of the Ballybetagh bogs, the classical site for remains of the Irish 'elk', yielded a collection of northern or highland types of plants apparently of a date prior to the post glacial birch epoch

University and Educational Intelligence

CAMBRIDGE —Mr. K W M Pickthorn, fellow and tutor of Corpus Christi College, has been returned unopposed as National Conservative member of Parliament for the University. His was the only nomination for the seat vacant by the resignation of Mr. G H A. Wilson (Conservative), Master of Clare College, who is to be the next vice-chancellor of the University

LONDON —The Senate, at its meeting on February 21, approved a proposal to hold external examinations of the University in New York This proposal, which is an entirely new departure in the history of the University, was submitted by His Excellency the American Ambassador and the British Foreign Office to the State Department in New York, which has given its formal sanction. These examinations are to be available for both British subjects and students of other nationalities

The Court has accepted the offer by the Radcliffe Trustees of the Radcliffe 24-in refracting telescope, which was the main instrument of the Radcliffe Observatory in Oxford and has now been rendered available by the removal of this Observatory to South Africa It is hoped, so soon as funds can be obtained by the University for this purpose, to re-erect the Radcliffe telescope on the site of the present University of London Observatory in Mill Hill Park, where the Wilson 24-in reflector and the Fry 8-in refractor, as well as other instruments, are already housed

APPLICATIONS are invited for Lady Tata Memorial Research Scholarships in medicine, of £400 a year each, for research work in diseases of the blood with special reference to the leukæmias These scholarships are renewable annually up to a normal maximum of three years, and there are likely to be at least two vacancies for new candidates ready to begin work in October 1935 The scholarships are open to suitably qualified men or women of any nationality, and are ordinarily awarded on a whole-time basis. Applications must be made by April 15 Further particulars and forms of application may be obtained from the Secretary, Scientific Advisory Committee, 138 Bedford Court Mansions, London, W.C 1.

AMERICAN university statistics are exhibited and interpreted in an article by Dr. Walters, president of the University of Cincinnati, in *School and Society* of December 15 The outstanding feature of the returns is the reversal of the tide of enrolment, which has been ebbing since 1930 This recovery, which is much greater in institutions under public control than in

others, and is most pronounced in the mountain and south central States and least in New England and middle Atlantic States, is attributed to the following influences: financial aid for students from the Federal Emergency Relief Administration, the difficulty of finding employment for young people leaving school, improved economic conditions in some parts of the country and the persistent faith of parents in the value of higher education. 'Liberal arts' continues to be the most popular choice of entering students, although its percentage (72) of the total entries was slightly lower in 1934 than in the preceding year. Some striking increases in the entries into the various professional schools were: 48 per cent in agriculture, 27·5 per cent in commerce and business administration and 20·5 per cent in engineering. Another statistical article in the same issue directs attention to the fact that one tenth of the expenditure of Yale University last year was on assistance to students in need of financial aid.

Science News a Century Ago

Resumption of Work on the Thames Tunnel

The construction of Brunel's tunnel beneath the Thames from Rotherhithe to Wapping began in 1825, had been brought to a premature close in 1828, and for nearly seven years work was at a standstill. In 1834, however, a "Tunnel Club" was formed, principally by fellows of the Royal Society, and successful efforts were made to secure assistance from the Government for the completion of the tunnel. At a meeting of the shareholders held on March 3, 1835, in the City of London Tavern, the chairman announced that £247,000 in exchequer bills was to be advanced on the security of the property. He said that "the Company were much indebted to the late Government, as well indeed as to the present, for this aid. Great credit was due to all those who had advocated the grant of money, and among those who had formed the deputation to the Government were men of all parties. It had indeed, been the wish of all persons, at home and abroad, that this splendid work should be completed, and foreigners considered it a national disgrace that it should have been allowed to remain seven years without an attempt being made to complete it. The time, however, was not far distant when it was confidently believed this magnificent work would be completed." At the same meeting, Brunel made a report in which he said that on February 4 "the water-ways, which had been closed for several years were reopened, as a preparatory step for entering the shield. It was quite satisfactory to find that the infiltrations are very inconsiderable, and are just the same as they were before". The tunnel was opened to the public on March 25, 1843.

Bessel's New Method of Lunar Distances

An advertisement in *The Times* of March 8, 1835, announced: "This day is published, 8vo, 5s, BESSEL'S NEW METHOD OF LUNAR DISTANCES—Distances of the Sun and the four planets Venus, Mars, Jupiter and Saturn, from the Moon, calculated according to Mr. Bessel's method, together with their places for every day in the year 1835, to which is added, an Ephemeris of the Moon calculated for every third hour of mean Greenwich time upon M. Damoiseau's Tables; the culmination of the Moon for every day in 1835 for the Altona meridian, with the auxiliary quantities to reduce it to other meridians, and Tables for finding the Latitude by the Pole Star for 1835, calculated under the direction of H. C. Schumacher. John Murray, Albemarle St."

Sir Robert Peel and Mrs. Somerville

After offering a Civil List Pension to Airy, Sir Robert Peel wrote in March 1835 to Mrs. Somerville, saying, "In advising the Crown in respect of civil pensions, I have acted equally with a sense of public duty and on the impulse of my own private feelings in recognising among the first claims on the Royal favour those which are deserved from eminence in science and literature. ... In reviewing such claims, it is impossible that I can overlook those which you have established by the successful prosecution of studies of the highest order, both from the importance of the objects to which they relate, and from the faculties and acquirements which they demand. ... I am enabled to advise His Majesty to grant to you a pension on the civil list of two hundred pounds per annum, and if that provision will enable you to pursue your labours with less of anxiety, either as to the present or the future, I shall only be fulfilling a public duty, and not imposing upon you the slightest obligation, by availing myself of your permission to submit such a recommendation to the King." The pension was conferred on Mrs. Somerville and later, when Lord John Russell was Prime Minister, it was increased to £300 a year.

Death of Thomas Drummond

Early in March 1835, Thomas Drummond, the botanical collector, died at Havana, after spending ten years collecting in North America. The younger brother of James Drummond (1784?–1863) who investigated the botany of Western Australia, Thomas Drummond began life as a nurseryman in Forfar, but became known to botanists by distributing sets of mosses. In 1825 he was selected as assistant naturalist to Dr. (afterwards Sir John) Richardson in Sir John Franklin's second land expedition in connexion with the discovery of a North-West Passage. He accompanied the expedition westward by the Hudson and Lakes Ontario and Winnipeg to the Mackenzie River, but quitted the main party at the Rocky Mountains. His subsequent botanical expeditions took him on foot across the Alleghany Mountains to St. Louis, to New Orleans and to Texas. At Velasco he was attacked by cholera but was afterwards able to continue his excursions. He finally embarked for Havana on February 9, 1835. The plants he sent home were described by Sir William Hooker in his "Flora Boreali Americana", his "Journal of Botany" and in the "Companion to the Botanical Magazine".

Objects for the Microscope

In the *Records of General Science* of March 1835 under the heading "Scientific Intelligence", it is stated that "Mr. Andrew Pritchard, Pickett Street, Strand, has just published a useful little work for such persons as take an interest in examining the beauties of the minute works of nature. It consists of a list of 2000 microscopic objects, and is intended to serve as a guide for selecting and labelling subjects of natural history, botany and mineralogy. Some good observations are prefixed in reference to mounting microscopical subjects, with remarks on the circulation of animals and plants."

Societies and Academies

LONDON

Royal Society, February 21. F W ASTON The isotopic constitution and atomic weights of hafnium, thorium, rhodium, titanium, zirconium, calcium, gallium, silver, carbon, nickel, cadmium, iron and indium. Mass-spectrograph analyses both by anode rays and the ordinary discharge have been made of thirteen elements Rays from some twenty new isotopes were discovered in all The atomic weights estimated by the photometrical measurements of abundance are generally in good accord with the accepted ones In the case of cadmium, success was attained in an unexpected manner and interesting observations were made on the behaviour of metallic methyls in the discharge Work on the isotopic constitution of elements is now fairly complete All but four, palladium, iridium, platinum and gold, have given positive results of some sort Some 247 stable isotopes are known and one of the most astonishing facts revealed is the occurrence of a stable elementary atom for practically every natural number up to 210 J M STAGG The diurnal variation of magnetic disturbances in high latitudes For some years it has been known that irregular, short-period perturbations ('disturbances') in the earth's magnetic field at a few isolated localities have a daily variation in their time of incidence, but it was not known whether the variation is governed by local or universal time or how it is affected by magnetic latitude Using the records from ten magnetic observatories in both hemispheres, it has been established that short period irregular disturbance is controlled by local time up to the magnetic axis pole Below magnetic latitude 70°, the variation in disturbance has a dominant single maximum in the late evening throughout the year, above 80° its phase is reversed and the transition from summer to winter conditions involves radical change both of type and scale In the intermediate zone the incidence of disturbance varies also with season and with the state of general disturbance, both forenoon and evening maxima being conspicuous

MOLOTKOVKIJ: Determination of the coefficient of ventilation in leaves. The coefficient of ventilation is the volume of air, in cubic millimetres, passing through one stoma in a second. A method for its determination is described. I. KOLOMIEC: Scheduling the dates of watering and drought in accordance with the stages of plant growth as a means of controlling the yield. A. VACENKO Inheritance of glume pubescence and of the black colour of the ear in *T. durum*. A. SVETOVIDOV: Geographical variability of *Coregonus lavaretus pidschian* V ARGAMAKOVA: Some Ophiuræ from the east coast of Sakhalin *Ophiocten miocaenicum*, another *Ophiocten* species and *Amphiophiura aenigma* are described from Miocene deposits of the Island of Sakhalin.

SYDNEY

Royal Society of New South Wales, November 7 J C EARL and H. M. PARKIN The fastness of certain aminoazo dyes to washing Aminoazobenzene and its N-methyl, NN-dimethyl, N-benzyl and NN methyl benzyl derivatives were studied comparatively as regards the fastness to washing of dyeings on wool made with them under exactly similar conditions The p-sulphonic acids of the last four of the above compounds were also compared In both series the NN-methyl benzyl derivatives were very much faster to washing than the other dyes. F. P DWYER and D P MELLOR: Compounds of palladium with benzildioxime An investigation of the compounds of palladium with the isomeric forms of benzildioxime has shown that palladium is strictly analogous to nickel, in that one molecule of the metal is co-ordinated with two molecules of α (anti)-benzildioxime and with one molecule of γ (amphi) benzil dioxime However, unlike all the common metals and the other metals of the platinum group, palladium gives an insoluble compound Pd ($C_{14}H_{10}N_2O_2$) with β (syn)-benzildioxime J G CHURCHWARD Note on the occurrence in New South Wales of black chaff of wheat caused by *Bacterium translucens*, var *undulosum*, S J and R Infected stems, leaves, chaff and grain of commercial and other varieties were found in several wheat-growing districts in New South Wales Work at the University of Sydney would suggest that the disease is widespread and has been present in New South Wales, unrecognised, for a number of years The extent of the losses caused by it are not yet known A number of the most popular varieties of wheat in New South Wales are susceptible C C TOWLE: An inquiry concerning a certain conventionalised type found along the coast of New South Wales Of the flaked stone implements found, the conventionalised types are essentially asymmetrical in form, and various interpretations have been given concerning the uses to which they were put by the aborigines Systematic inquiry shows that the most probable reason for the asymmetrical form of the implements was the highly refractory nature of the material available for flaking For several reasons, the flakes of this form produced the most satisfactory implements The conventionalised implements dealt with in the paper have been classified as scrapers, and they have been correlated with some of the conventionalised scrapers from the far western areas of New South Wales The implements from those parts where a tractable material was available are more symmetrical in form M. B. WELCH The moisture equilibrium of timber in different parts of New South Wales (2) Murwillumbah. During the period October 1930–October 1932, a moisture equilibrium investigation was conducted at Murwillumbah, New South Wales. It has been found that in general the atmospheric humidity conditions are higher than at Sydney, and the mean moisture content of ten different timbers kept indoors over the period was 13 2 per cent, whereas similar timber under the same conditions at Sydney showed a mean of 12 0 per cent. Periods of very high humidity were found to occur during which the mean monthly moisture content for timbers such as tallowwood and blackbutt was in the vicinity of 16 per cent and Queensland maple exceeded 17 per cent. During such periods, satisfactory air seasoning of timber for the Sydney market does not appear to be practicable.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public*]

Monday, March 4

BRITISH MUSEUM (NATURAL HISTORY), at 11 30.—Dr. Susan Finnegan "Arachnids Injurious to Man".*

UNIVERSITY OF CAMBRIDGE, at 5 —Sir Daniel Hall: "The Pace of Progress" (Rede Lecture) *

UNIVERSITY OF LEEDS, at 5 15 —Prof F A E Crew "Biology and Human Affairs".*

KING'S COLLEGE, LONDON, at 5 30 —Prof J S Lee "The Geology of China considered in Relation to Secular Movements" (succeeding lecture on March 11) *

ROYAL GEOGRAPHICAL SOCIETY, at 8 30 —Prof E P Stebbing "The Encroaching Sahara"

Wednesday, March 6

ROYAL SOCIETY OF ARTS —Sir Henry Richards · "The Problem of Noise"

SOCIETY OF PUBLIC ANALYSTS, at 8 —(at the Chemical Society's Rooms, Burlington House, Piccadilly, W 1) — Annual General Meeting

Dr. Bernard Dyer An Address giving Reminiscences of the Society and some of its Prominent Members

BRITISH SCIENCE GUILD AND ROYAL INSTITUTION, at 9 —(at the Royal Institution) —Sir Frederick Keeble "The Fertility of the Earth" (Research and Development Lecture)

Thursday, March 7

BEDFORD COLLEGE FOR WOMEN, at 5 15 —Sir Arthur Eddington "Time and Entropy" *

Friday, March 8

UNIVERSITY COLLEGE, LONDON, at 5.—Dr. A. Michels. "Some Results of High Pressure Measurements in Gaseous and Liquid Systems" (succeeding lecture on March 15) *

ROYAL INSTITUTION, at 9 —Sir John Russell · "The Future of British Agriculture".

SOCIETY OF CHEMICAL INDUSTRY, March 8.—Conference on Meat to be held at the University of Liverpool
3–5 "The Chemistry of Meat"
6–7 30 "Meat Storage"

INSTITUTE OF METALS, March 6–7 Annual General Meeting to be held at the Institution of Mechanical Engineers, Storey's Gate, London, S W 1

Rationalisation of Scientific Publication

THE social aspects of scientific research, and the view that men of science should take a much more prominent part in spreading a scientific outlook and approach to social and other general problems of the community, have been eloquently urged in recent months Despite these new opportunities and the greater disposition to listen to the contribution he can offer in these matters, the scientific worker often remains his own worst enemy The lack of progress, for example, with all attempts to rationalise the publication and abstracting of scientific literature, or towards effective co-operation between scientific societies, continues to demonstrate an inability of the scientific worker to set his own house in order, if indeed it does not expose him to the charge of fiddling while Rome burns Conservatism can be preserved from inertia and ineptitude only by wise judgment and the assimilation, not the rejection, of new ideas

There are, of course, conspicuous exceptions The Oil and Colour Chemists' Association, for example, has recently appointed a research and development correspondent whose special task is to assist in the interpretation of the results of the latest research work in a form which is easily assimilated by the industry or by the public This is a welcome sign of the recognition of the need for expositors or interpreters of science if industry and society are to utilise to any wide extent the scientific knowledge which is already available for them, apart altogether from the penetration of science into the new fields of social research The laxity of scientific men generally in regard to the exposition of their results, the widespread use of jargon, the inability of many scientific workers to express themselves in concise and accurate English, are serious obstacles to the spread of scientific knowledge into the sphere of political action Even in industry, startling examples are often encountered of the indifference of the research worker to the reporting of his results in terms intelligible either to other scientific workers or those responsible for management The industrial worker often remains ignorant of, and amazingly indifferent to, the contrast between the meticulous accuracy of his experimental work and the careless and ambiguous manner in which he presents his results He does not appear to realise that lack of care at this point may vitiate his work as effectively as inaccuracy in the laboratory

In consequence of this neglect, besides the difficulty placed in the way of the assimilation of scientific investigations into industrial or social practice, the scientific worker adds to the burden of publications of which he is often the first to complain Looseness of thought, and indifference to the accurate and correct use of words, are a prime cause of the redundancy noticeable in many scientific papers Dr H Moore was undoubtedly justified in stressing this point in his presidential address last year to the Institute of Metals There are few papers indeed which would not have gained both from a scientific and from a literary point of view by careful revision, the exclusion of all irrelevant matter and the choice of the simplest and fewest words to express the author's meaning As Dr Moore pointed out, a clear idea of what he is doing and why he is doing it is as essential to the research worker in writing his paper or report as it is in the conduct of his experiments A command of terse pregnant English is a valuable possession to the writer of a scientific paper, and is worth much trouble and patience to acquire One of the merits of abstracting work as carried out in the past under the Bureau of Chemical Abstracts and elsewhere has been the discipline it imposes on the abstractors in regard to conciseness and clarity Apart from the knowledge the abstractor acquires of his science, it enforces precision of language which should be a great asset in the writing of papers in subsequent life, and should exemplify, to him at least, the way in which force and clarity are related to brevity

Dr. Moore estimates that the length of a scientific paper might well be reduced by about twenty per cent in this way, with advantages both in clarity and in diminished printing and publishing costs , and this reasonable estimate is sufficiently large to indicate that the matter is one well worth close attention by scientific societies One of the difficulties is, however, the lack of perspective which sometimes characterises scientific writers—a failure to see their topic in its true relation to the science as a whole, and a tendency to claim, for the normal or average, the fuller and more detailed treatment which should be the privilege of those few papers which describe some really outstanding achievement or advance

This question of values cannot be evaded. It is essential in the investigator alike in planning, executing and describing his work. It is equally essential when we confront the large question of the rational treatment of the mass of scientific literature to-day and the most efficient distribution of the burden To its absence must be attributed the duplication of abstracting work which still persists, in regard to chemical literature, despite the example of co-operation afforded by the Society of Chemical Industry and the Chemical Society for nearly ten years That it is difficult to avoid overlap between different fields such as chemistry, entomology, physiology, physics and engineering, etc , is obvious, though even here co-operation is less difficult than is imagined by the superficial The duplication within any one field such as is provided by the abstracts of the Society of Public Analysts or the Society of Dyers and Colourists, to cite only two examples, which merely re-issue in varied form and at a later date the substance of abstracts provided for the whole science or profession by the Bureau of Chemical Abstracts, is surely remediable Powerful arguments might be addressed in favour of the State contributing towards the cost of scientific publications, but support is unlikely to be given before men of science themselves eliminate the duplication of effort to which we have referred

The waste and duplication are not confined, however, to abstracting publications The same confusion of thought is to be found in regard to other types of publication as a result of the sectionalism and excessive specialisation in which such a profession as chemistry abounds Each group pursues its own interests and special requirements without regard to those fundamental needs which must be served if its own specialisation is even to be possible The net result is an intolerable burden on the parent and more comprehensive societies, such as the Chemical Society, which is appreciably enhanced by the marked reluctance of the younger members of the profession to support such societies by actual membership as compared with a couple of decades or so ago

Chemists are probably neither better nor worse than other scientific workers in these matters, but if they and other men of science tend to lament rather too freely the burden which membership of numerous societies or the cost of publications places upon them, they should remember that the remedy is largely within their own hands. The setting of their own house in order would be a sure way of establishing the confidence of the community in the capacity of scientific workers for the wider fields of social service now opening before them.

Two Historical Notes

By PROF E N DA C ANDRADE, University College, London

HUMPHRY DAVY'S EXPERIMENTS ON THE FRICTIONAL DEVELOPMENT OF HEAT

IN practically all textbooks on heat, certain experiments of Humphry Davy are cited as constituting early experimental proof of the dynamical theory of heat, and they are generally said, either directly or by implication, to be of major importance There is a certain amount of variety in the description of what these experiments were several authors (for example, Poynting and Thomson, Grimsehl, Loeb and Adams and Hoare) say that he rubbed the pieces of ice together in a vacuum, while others (for example, Edser and Preston) say that he performed the experiment in air, and afterwards carried it out *in vacuo* Now any physicist who contemplates repeating the experiment will, I think, at once be struck with the difficulty, if not impossibility, of carrying it out in such a way as to produce anything in the nature of a convincing result If the ice is covered with a film of water, the friction is so small that scarcely any work is done, while if it is really dry it is liable to stick In any case, to make the frictional heat appreciable, it is necessary to have a normal force holding the two surfaces together, and then one gets the well-known lowering of freezing point and consequent melting, if the surroundings are at the ice point, with all the possible dangers of regelation at the edges Again, the amount of work required to melt 1 gm of ice is very large the criterion is an extraordinarily insensitive one All these difficulties are, perhaps, sufficiently summarised in the fact that nobody, apparently, has ever tried to repeat the experiment, and I, for one, would not care to undertake it

It is, then, perhaps worth while pausing a moment to inquire just what Davy did, and in what circumstances The account of these and certain other experiments was the author's first contribution to science, and was published (in "Contributions to Physical and Medical Knowledge, principally from the West of England", edited by Thomas Beddoes, father of the poet Thomas Lovell Beddoes) early in 1799, when he was twenty years old The work was, then, presumably carried out when he was nineteen The first experiment described is directed to show that light is not an effect of heat, he held that he had proved experimentally that particles of iron can be heated to the melting point without giving out light! The second and third are the celebrated ice experiments

In the first of these, described in less than three hundred words, without any detail, Davy says that he fastened two pieces of ice by wires to two iron bars and that "by a peculiar mechanism" the ice was kept in violent friction for some minutes The pieces of ice "were almost entirely converted into water" which, strangely enough, was found to be at 35° "after remaining in an atmosphere at a lower temperature for some minutes", or, in other words, the friction of ice can raise water many degrees above the melting point! Even supposing that the stroke of the 'engine' was 5 cm, and that it executed 100 strokes a minute, and that the coefficient of friction was 0 5, this would mean, if for "some minutes" we read "ten minutes", that the force pressing the pieces of ice together would have to be equivalent to an additional pressure of about 4 atmospheres The whole experiment is fantastic This is said in no disrespect to Davy how could one expect an untrained boy in 1799 to carry out an experiment which even to-day would tax an experienced physicist, to say the least? No doubt the whole effect observed by Davy was due to conduction

The second experiment, the one in a vacuum, was not concerned with ice at all, but with the melting of wax The wax was apparently attached to a metal plate, against which rubbed a clockwork-driven wheel The clockwork stood on a piece of ice in which was cut a channel containing water, and the whole was under an exhausted bell-jar The argument was that if the heat required to melt the wax had passed from the ice to the clockwork, the water would have frozen As, however, the heat required to produce the rise of temperature observed in the clockwork amounted to but 12 calories, only 0 15 c c of water would have frozen in any event, which actually could not be observed by eye in a rough channel cut in a piece of ice The experiment proves nothing at all

I may be held to have spent too much time on a point which some may say is of historical interest only I hold, however, that it is very inadvisable that students should be taught to attach a fundamental importance, not to experiments crudely carried out, which were afterwards improved, but to experiments of which one probably cannot be carried out at all, while the other is so ill-designed as to prove nothing I am no denigrator, I do not think that it detracts from the greatness of Davy to point out that his first experiments, carried out when he was a country lad, were uncritical and lacked all quantitative basis It is time, however, that they ceased to be ranked with such convincing demonstrations

as those of Rumford, and disappeared from the textbooks Or, if they are quoted, do let us have instructions as to how to melt two pieces of ice by rubbing them together in a vacuum

Newton's Early Notebook

In the Isaac Newton Memorial Volume, produced in 1927 to commemorate the two hundredth anniversary of Newton's death, there was published for the first time the contents of an early notebook, compiled by Newton as a boy or young man The first part consists of a collection of rules and hints relating to drawing and painting (how to shade, how to enlarge a picture, to make a russet colour and so on), of receipts for cements, baits and other odd things, of cures for certain troubles, and of tricks Prof David Eugene Smith, who edited this matter, attributes it to some time within the period 1655–58 and apparently takes it to have been compiled by Newton Prof Louis Trenchard More, in his life of Isaac Newton, published last year, comments "The most interesting, perhaps, of the items in this book, are those referring to drawing and the making of pigments, as they show the great interest he took in the art, and to the chemical and medicinal recipes which he jotted down"

This part of the notebook is, however, no collection of Newton's own, but is copied out from a book of receipts popular at the time, namely, John Bate's "The Mysteries of Nature and Art", of which the first edition was printed in 1634, and the third and last edition (a copy of which is in my possession) in 1654, shortly before the period to which we must attribute the part of the notebook in question With this edition I have checked off all Newton's rules for drawing and painting, and many of his odd receipts—in fact, everything down to and including "To ingrave on a flint" in Prof David Eugene Smith's reprint The small remainder of this part of Newton's notebook consists of a few medical prescriptions and conjuror's tricks, which he may have picked up while lodging with Mr Clark, the apothecary I have not been able to trace them

Another point of interest in Bate's book is that it contains full directions for making a water clock, which correspond to the account which Dr Stukeley* gives of the water clock undoubtedly made by Newton There is no doubt, then, that the "Mysteries of Nature and Art" was a book which young Newton freely consulted, and I conjecture that profounder historians than myself will find that it well repays study

I may add that I find it a little difficult to accept Prof Smith's attribution of date, 1655–58, for the first part of the notebook On the first page of the book is the inscription

ISAAC NEWTON HUNC LIBRUM
POSSIDET
TESTE
EDVARDO SECKER
PRET 2d OB
1659

Now, while a boy might write his name in a notebook, with his signature witnessed, as a schoolboy joke, some time after purchase, he is very unlikely to put the price, in this particular instance 2½d, except at the date of purchase We know that Newton was very careful in his accounts of expenditure I think we must take it that this inscription was inserted when the notebook was bought, and gives the date of the first entries

* See Brewster's "Life of Sir Isaac Newton", vol 1, p 9 Louis Trenchard More, "Isaac Newton", p 12

Centenaries of Newcomb and Schiaparelli

SIMON NEWCOMB and Giovanni Virginio Schiaparelli were born within two days of one another, the former at Wallace, Nova Scotia, on March 12, 1835, and the latter at Savigliano, Piedmont, on March 14, and they died within a year of one another, Newcomb passing away on July 11, 1909, and Schiaparelli on July 4, 1910 Counting among their most distinguished contemporaries Lockyer, Huggins, Gill, Janssen, Loewy, Otto Struve, Auwers, Asaph Hall, Langley and Young, Schiaparelli was long regarded as the foremost of Italian astronomers, while Newcomb became to be recognised as the most eminent man of science in the United States

They devoted themselves to widely differing branches of astronomy Newcomb, as a member of the staff of the Naval Observatory, Washington, and as head of the "American Ephemeris and Nautical Almanac", during the course of forty years, contributed greatly to the advancement of gravitational astronomy, while Schiaparelli added immensely to the knowledge of meteors, comets and the planets Honours were bestowed on them by many societies and institutions, both were associates and medallists of the Royal Astronomical Society, both were foreign members of the Royal Society and foreign associates of the Paris Academy of Sciences, while Newcomb's connexion with the United States Navy was recognised by Congress granting him the rank of a rear-admiral.

Of Newcomb, many appreciations were written after his death in 1909, but the most fascinating

record of his life is his own "Reminiscences of an Astronomer", published when he was sixty-eight years of age In this, when speaking of Cayley the mathematician, he said, "His life was that of a man moved to investigation by an uncontrollable impulse, the only sort of man whose work is destined to be imperishable" The remark might well apply to Newcomb himself, for when at the age of twenty-two years, after an unusual start in life—which had included two years' service under a quack doctor—he entered his own "world of sweetness and light" as a computer in the office of the "Nautical Almanac" at Cambridge, Mass, his genius found the avenue which was to lead him to the highest distinction

Of his work, his travels and his friendships of the years 1857–77, Newcomb gave an account in the early chapters in his "Reminiscences" "On September 15, 1877," he went on to say, "I took charge of the Nautical Almanac Office The change was one of the happiest in my life I was now in a position of recognised responsibility, where my recommendations met with the respect due to that responsibility, where I could make plans with the assurance of being able to carry them out " He was editor of the "American Ephemeris and Nautical Almanac" for twenty years, and his most valuable work for science was done in connexion with it It was this work which led to his being awarded the Copley Medal in 1890, and being elected a foreign associate of the Paris Academy of Sciences in 1895, in succession to Helmholtz

A devoted public servant and an indefatigable worker, Newcomb set an inspiring example to all with whom he came in contact, while, said Sir Robert Ball, "His habitual loftiness of thought, nobility of character, dignified courtesy and ever-ready helpfulness endeared him to his many friends on both sides of the Atlantic"

Schiaparelli was far more fortunate than Newcomb in his early environment, and at the age of nineteen years graduated from the University of Turin in engineering and architecture For a year or two he taught mathematics, but astronomy had already laid its hold upon him, and in the year that Newcomb began his work at Cambridge, Schiaparelli was able to enter the Berlin Observatory, then directed by Encke, and two years later secured a post at Pulkovo under the Struves Recalled to Italy in 1860 to become assistant to Carlini at the Brera Observatory, Milan, in September 1862 on the death of Carlini he was made director of the Observatory and this post he held for thirty-eight years

Schiaparelli's first year at Milan was marked by his discovery of the asteroid Hesperia Four years after becoming the director, he announced his discovery of the connexion between meteors and comets, and in 1873 he published his "Le Stelle Cadenti", declared by Lockyer to be one of the greatest contributions to the astronomical literature of the nineteenth century In 1877 he commenced his observations of Mars, in 1882 began the study of Mercury and Venus and between 1875 and 1899 made 11,000 measures of double stars Failing sight brought an end to his observations, and in 1900 he retired Among his later work was his book on the astronomy of the Old Testament, in the preparation of which he had examined the dates of 2,764 Babylonian documents which had been translated

Schiaparelli's views on the so-called 'canals' on Mars led to much controversy, and it is worth recalling that it was this which reawakened Lowell's interest in astronomy and led him to erect the Lowell Observatory, at Flagstaff, Arizona, where just five years ago the planet Pluto was discovered

Modern Plastics

SOME criticism has been made of the word 'plastics' as applied to the industry which goes under this name to-day The word 'plastics' is usually associated with clay, putty or similar materials which can be worked and shaped by hand But 'plastics' has not, even in the past, been limited to materials which retain their plasticity Clay, having been moulded into shape while in a plastic condition, takes permanent form after baking, but the article in its permanent form is still classified in the 'plastics' group The bulk of the products of the plastics industry in its modern form may similarly be characterised—initially plastic, they are converted by heat and pressure into permanent forms.

Bayer in 1872 first announced that phenols would react chemically with formaldehyde, but beyond this fact little further attention was paid by him to the product Other workers investigated the reaction later, and Kleeberg in 1890 first discovered that it was not a pure product that was obtained, but a sticky viscous material Then technical men more commercially minded came into the field and started investigations One of the early patents was taken out by Luft in 1902, who described a horn-like material which could be turned and shaped into various articles He described it as artificial horn Others followed, but none of them appears to have made a material which was commercially useful, since they found

no means of controlling the reaction or arriving at a reliable or satisfactory end-product

Certain firms in Great Britain and in the United States began to develop the condensation product in liquid form for varnish purposes, but not until Dr Baekeland turned his attention to this reaction was progress made Dr Baekeland announced his new discovery in 1908, and applied for patents in most countries in the world The basis of his invention consisted in the use of relatively small proportions of ammonia as an accelerator in the reaction between phenol and formaldehyde, as against large amounts of acid or alkali used hitherto He found that by the use of a small amount of alkali, the reaction could be controlled and checked at a convenient point during its progress, this resulting in an intermediate product between the raw materials and the final end-product obtained previously, which was hard, brittle and non-plastic

All previous workers on this product had obtained a crystalline product or a hardened mass which was of little value Dr Baekeland succeeded in producing a material which could be used commercially It could be readily handled, being a resin-like solid which could be ground, powdered, softened or dissolved in solvents This he termed Bakelite 'A' This product was chemically changed on the application of heat by polymerisation into a permanently hard amber-like solid which would no longer soften by heat, had good insulating properties and was termed Bakelite 'C' When mixed with fillers in a powdered state, it could be introduced into steel moulds, subjected to heat and pressure in hydraulic presses, and, by continued application of heat, it set solid and assumed the shape or the contour of the mould into which it had been pressed, and could be discharged permanently solid This process is the basis of the modern plastic moulding industry to-day

The early material of Dr Baekeland's invention was somewhat variable in quality and slow in its rate of hardening in the mould to the 'C' stage, and consequently the moulding industry made slow headway. It was in a very elementary stage, and it was not until towards the end of the War that practical advancement in the technique of manufacture of what are now termed the resinoid moulding powders, showed any progress in Great Britain The last fifteen years has brought about considerable change in the industry and its technique. Where twenty-five years ago the moulding materials consisted of the resin A, ground to powder and mixed with dye and wood-meal, of which the rate of hardening was 5–15 minutes for an article of relatively small size, to-day similar articles are turned out from complex moulding mixtures at the rate of 1–1½ minutes in multiple impression moulds having as many as 50–75 impressions , so that where one article was produced in five minutes, we have to-day 200–250 of the same articles turned out in the same time

The production of mouldings has been referred to as illustrating the advancement of one side of the resinoid plastics industry Dr Baekeland's invention led to the production of other useful materials, apart from mouldings for the electrical and allied industries It was found that, when this Bakelite Resinoid A was dissolved in solvents, and paper sheets were impregnated with it and then dried and pressed together in a hydraulic press between steam-heated platens, the resinoid hardened and made a compact mass consisting of laminations of paper sealed together by the hardened resinoid , the product was 'Bakelite laminated sheets' This material was found to be very hard and tough, yet it could be machined and had excellent insulating properties It found a ready application in the electrical industry The advancement in this branch of the industry has been less spectacular than in the moulding section, but advances have been made The methods employed in production to-day are very much the same as when this material was originally introduced, apart from minor improvements in plant, but I feel sure we can look for great advances in methods of production, cheapening in costs and widening its applications

Until the last year or two, the production of mouldings had been confined to small articles chiefly for the electrical industry, such as switch cover plates, distributor heads for car ignition sets and picnic set requisites and many similar products With the introduction of radio sets at a price to attract the masses, the question of the production of cabinets to house the sets was considered by those concerns which turned their attention to the production of such sets in large quantities in standard and uniform design It then became evident that a case or housing for such sets could be produced in plastics more fitting in design to meet modern requirements at prices to compete with those constructed of wood This led to the production of the moulded radio cabinet, of which there are many examples to be seen to-day. The production of these cabinets called for the installation of very large and expensive hydraulic presses and moulds costing several thousands of pounds. The very existence of these presses will, no doubt, have the effect of leading the industry into the production of larger mouldings. The general tendency will be towards the production of still larger articles in moulded plastics, each moulding requiring many pounds of powder, thus gradually supplanting many articles and parts of articles at present made in wood or metal by plastic

moulded articles made on mass production lines When this comes about, it is obvious that designs will have to change to meet the modern technique of production

Very serious artistic thought should be given to the designs for the future, in order that such production may not only be practical from a mass production point of view, but also both restful and pleasing to the eye in outline and colour In that way they will establish for themselves a permanent future and not be just a 'five minute wonder' to die out for lack of permanent artistic foundation This is a point to which the industry should pay attention if it desires to establish itself as one of the main industries of the future

The laminated material referred to above is at present relatively new compared with the moulding industry Its chief applications have been industrial, in so far that it has formed a part in a main assembly, that is, in its use for insulation purposes in electrical equipment Now, however, the material can be produced in sheets of larger sizes and in various colours and finishes, and it is already finding a use in industries that cater for domestic requirements The laminated sheet material has some valuable features as it is resistant to heat, not readily marked or scratched, unaffected by alcohol and other solvents, and can be highly polished Such properties are of value for many domestic applications It is used for tops of tables in cafés, for dressing-table tops in hotels In the United States it has been tried out as panelling for ships, state-rooms, cocktail bars, and similar applications are under trial in Great Britain There are many uses for this material not yet developed, as it is difficult to find any other class of product which exhibits similar properties There is no doubt that we shall see large developments in its use during the next few years When sheets of this product are available in pleasing soft colours, they are likely to find favour for room decoration, for which, in many ways, they are ideal

Future designs will require careful thought and planning Present ideas do not entirely fit in with production of this type of material, and a new art and technique will have to be developed to meet these new products Many articles which were previously made by hand, in many cases elaborately decorated by the craftsman, will in the future be produced in mass by this new process of moulding and fashioning For a time, the craftsman's hand on the finished article will disappear until the industry has so advanced its technique that present difficulties of production have disappeared, then, there will be room for the craftsman to exercise his art—not on the finished article or on its construction, but in the steel or other material forming the master model from which such articles will be produced, and by engraving into it pleasing designs and artistic ideas which will be effectively and correctly reproduced in detail on the moulded articles By these modern processes, such articles will be manufactured in quantities which will enable them to be sold at prices within the purchasing capacity of the majority

H V POTTER

Obituary

DR R C. KNIGHT

SCIENTIFIC horticulture has suffered a heavy loss by the death on January 28 of Dr R C Knight, assistant director of the East Malling Research Station He was born in 1891 and was educated at Sexey's School, Bruton, Somerset, and at the University of Bristol, where he took a degree in botany He obtained a Board of Agriculture research scholarship in plant physiology in 1916, which he held at the Imperial College of Science and Technology, and in 1919 he was appointed to the staff of the Research Institute of Plant Physiology of that College His association with East Malling Research Station began in 1920, when the demonstration of striking examples of rootstock influence upon the scion opened up a promising field for physiological investigations. At first Dr Knight merely visited the Station for short periods to familiarise himself with his problems and to collect the necessary material By 1922 it became obvious that in order to push forward with the work he must live on the spot with his material, and he was seconded for duty at the East Malling Station, where he worked until his death.

So wide were Knight's interests that he rapidly became familiar with the horticultural problems being investigated around him, and although he often said that these early years were "spent in closing doors by obtaining negative results rather than in opening them", this was an essential preliminary exploration, and he was all the time evolving in his mind and discussing with his colleagues those 'physio pomological' methods which he used so much in later years While he did much careful work in determining the optimum conditions for raising hard-wood and soft wood cuttings, his outstanding contribution was concerned with the practice of layering Here he emphasised and elucidated the all-important part played by the etiolation of the base of the shoot in encouraging adventitious rooting By directing attention to this aspect he made it possible to reproduce with much greater certainty clonal races of a far wider range of plants than had been possible heretofore

Knight's contribution to horticultural science, however, is in no way measured by the twenty or more published reports standing under his name He exercised

a profoundly stimulating influence not only upon his immediate colleagues, but also upon the large number of graduate workers and investigators on leave from overseas who visited the Research Station for long or short periods

Much of Knight's thought and care is built into the structure and equipment of the laboratories and library, but after these are forgotten his informal methods of evoking stimulating discussion, his unobtrusive readiness to give good counsel and frank criticism, and his gift for inspiring confidence will long be remembered by his colleagues

DR HERBERT WELD

WE regret to record the death at the age of eighty-three years of Dr Herbert Weld, geographer and archæologist, which took place at Lulworth Castle, Dorset, on February 4

Dr Weld was best known as an authority on the history and geography of Abyssinia, parts of which country he was the first to map Of recent years, however, his name has more frequently been before the public in connexion with the exploration of Kish in Iraq by the Oxford University Expedition under Prof S Langdon, for which he was responsible, obtaining the concession at Tell Aheimar while in Iraq in 1922, and financing the expedition, which began operations in the following year In addition to a large number of antiquities and an invaluable store of archæological data going back to the earliest stages of human occupation of the country, the expedition acquired some thousands of inscribed tablets These, with such of the antiquities as were allotted to the expedition, were presented to the Ashmolean Museum at Oxford

Herbert Weld (formerly Weld Blundell) was the son of Thomas Weld-Blundell of Ince Blundell, and was educated at Stonyhurst and Queen's College, Oxford, from which university he afterwards received the honorary degree of D Lit in recognition of his work in connexion with the expedition to Kish Before his exploratory work in Abyssinia he had already travelled in Persia (1891), Libya (1894), where he visited all the oases in turn, and Cyrenaica (1895) While in Persia he visited Persepolis and took a number of moulds of the reliefs, which he presented to the British Museum and the Louvre. He also prepared a scheme of restoration which was eventually utilised His first visit to Abyssinia took place in 1898–99, when he travelled from Somaliland to the Sudan, bringing back a large collection of birds, including seventeen new species, which he presented to the British Museum (Natural History) In 1905, after the interruption of the South African war, where he was present as a newspaper correspondent, he was again in Abyssinia, continuing his work of mapping and collecting. On this occasion he covered the previously unmapped course of the Blue Nile from Tsana to the Sudan He had already been a contributor to the *Geographical Journal*, the "Annual" of the British School at Athens and the *Journal of the African Society*, when in 1923 his Abyssinian studies bore further fruit in a highly valued volume, "The Royal Chronicle of Abyssinia, 1769–1840", of which the text, in translation from the "Ethiopic Chronicle" in the British Museum, was accompanied by learned and informative appendixes.

PROF R A ROBERTSON

ROBERT ALEXANDER ROBERTSON, born in Rattray, Perthshire, in 1873, was a graduate in arts and in science of the University of Edinburgh Going to the University of St Andrews in 1889, he was appointed lecturer in botany in 1891, his status being raised to that of reader in 1915 In 1920 a chair of botany was instituted and Prof Robertson became its first occupant He retired in September 1934, and died on January 15 last

Robertson was a great teacher Not only had he the power of imparting knowledge, but he also developed initiative and created enthusiasm In his early years at St Andrews he provided many examples from the vegetable kingdom to illustrate the then new conception of 'functional inertia' advanced by Fraser Harris In those days, too, recognition of timbers by their microscopic structure was pioneer work when illustrated by microphotographs

Prof Robertson was a fellow of the Royal Society of Edinburgh and of the Linnean Society He was a fellow of the Botanical Society of Edinburgh and its president in 1915 He was elected to the committee of management of the Imperial Bureau of Mycology from its inception in 1922 Prof Robertson commanded the St Andrews contingent of the O T C from 1912 until 1922

A man of great sympathy and of high principle, Prof Robertson strove in all things to do that which was best In this creed he gave forty-four years of strenuous service to his adopted University, and devoted a life to the advancement of botany in Scotland

PROF BASIL HALL CHAMBERLAIN, emeritus professor of Japanese and philology in the University of Tokyo, died at Geneva on February 15 at the age of eighty-four years At the time of his retirement from the University of Tokyo in 1905, he was widely recognised as one of the first authorities on the life and culture of the Japanese, avoiding the sentimentality and false idealisation which characterised most writers on the country of his day

WE regret to announce the following deaths.

Sir Leslie Mackenzie, medical member of the Scottish Board of Health from 1919 until 1928, and president of the Geographical Association in 1931–32, on February 28, aged seventy-two years

Sir William Morris, superintendent of the Ordnance Survey of the Transvaal and Orange River Colony in 1902–7, on February 26, aged eighty-eight years.

News and Views

New Fellows of the Royal Society

THE Council of the Royal Society has agreed to recommend for election into the Society the following seventeen candidates Dr N K Adam, research chemist, University College, London ; Prof E N. da C Andrade, Quain professor of physics, University of London ; Sir Frederick Banting, professor of medical research, University of Toronto, Prof S P Bedson, Goldsmiths' Company's professor of bacteriology, London Hospital Medical School, Mr E. J Bowen, fellow of University College, Oxford, Mr G E. Briggs, lecturer in plant physiology, University of Cambridge ; Prof H Graham Cannon, professor of zoology, University of Manchester, Prof W E le Gros Clark, Dr Lee's professor of anatomy, University of Oxford ; Prof J S Foster, professor of physics, McGill University, Montreal, Dr A. L. Hall, lately assistant director of the Geological Survey of the Union of South Africa, Dr W H Hatfield, Brown-Firth Research Laboratory, Sheffield, Dr J de Graaff Hunter, lately of the Survey of India ; Dr B A Keen, Rothamsted Experimental Station ; Prof. R A. Peters, Whitley professor of biochemistry, University of Oxford, Prof J. Read, professor of chemistry, University of St Andrews ; Dr R N. Salaman, director of the Potato Virus Research Station, Cambridge ; Dr R Stoneley, lecturer in mathematics, University of Cambridge.

New Fellows of the Royal Society of Edinburgh

AT the ordinary meeting of the Royal Society of Edinburgh, held on March 4, the following ordinary fellows were elected Dr J L Brownlie, chief medical officer, Department of Health for Scotland ; Dr R S Clark, scientific superintendent, Fishery Board for Scotland, Lieut -Col S H Cowan, lecturer in forestry engineering, University of Edinburgh, Mr C F. Davidson, geologist, H M Geological Survey of Great Britain, Mr Maxwell Davidson, lecturer in heat engines and thermodynamics, University of Edinburgh, Dr B N. Desai, assistant meteorologist, Government of India ; Dr R. Grant, demonstrator, Zoology Department, University of Leeds, Dr A M M. Grierson, senior assistant medical officer of health, Manchester, Dr A C. W. Hutchinson, dean of the Edinburgh Dental Hospital and School ; Dr J H Kenneth, assistant, Imperial Bureau of Animal Genetics, University of Edinburgh, Prof. Peter MacCallum, Pathology Department, University of Melbourne, Australia ; Dr. W. A. Mozley, Walter Rathbone Bacon scholar, Smithsonian Institution, 1931–34, Department of Zoology, University of Edinburgh ; Mr. J. Munnoch, formerly controller, General Post Office, Edinburgh ; Dr. B. Narayana, lecturer in physiology, University of Patna, India ; Mr C. S. Pichamuthu, assistant professor of geology, University of Mysore, India ; Mr. T. Rowatt, director, Royal Scottish Museum, Edinburgh ; Prof. M. G. Say, Department of Electrical Engineering, Heriot-Watt College, Edinburgh ; Mr Eric Stevenson, lecturer in Engineering, University of Edinburgh, Dr J D Sutherland, lecturer in psychology, University of Edinburgh, Mr J E Touche, Edinburgh, Sir William Whyte, solicitor, Uddingston

Sir C. V. Boys, F R S.

ON Thursday next, March 14, Sir C V Boys—more familiarly known as Prof Boys, though the honour of knighthood was conferred upon him by H M The King at the beginning of this year—will be eighty years of age, and his friends everywhere will, we are sure, be glad to associate themselves with us in offering him a tribute of esteem and congratulation on this event The Royal Society Club, of which Boys is the senior member, is to celebrate the occasion with a festival dinner, at which he will be presented with an album containing the autographs of members of the Club The Club consists of a group of fellows of the Royal Society who dine together on the days of the ordinary meetings It was formed so long ago as 1743, and its history has been related in a substantial volume by Sir Archibald Geikie entitled "Annals of the Royal Society Club", published in 1917 Benjamin Franklin was very frequently among the visitors in the latter half of the eighteenth century, and it is particularly appropriate to recall this association with the Club of the discoverer of the nature of lightning, and the recent work of Boys in the same field

SINCE 1752, when Franklin proved that lightning was an electrical discharge, and concluded that "for the most part, in thunderstrokes it is the earth that strikes into the clouds, and not the clouds that strike into the earth", practically no experimental work on the subject had been done until our new Franklin devised his rotating lens camera for the study of the propagation of the discharge Boys gave the first description of this ingenious instrument in an article entitled "Progressive Lightning" in NATURE of November 20, 1926 (118, 749), and its use in South Africa by Dr E. C Halliday, Dr B J F Schonland and Mr H Collens has shown that the majority of the lightning strokes examined consist of a dart-like downward-moving leader stroke, which may be described as an electron avalanche, followed immediately upon arrival at the ground by a more intense upward moving main stroke along thermally ionised channels. The device by which this new knowledge has been secured represents, like Boys's gas calorimeter, the production and use of quartz fibres for the determination of the gravitational constant and other purposes, the photography of rifle bullets and the study of soap bubbles, the application of most original conceptions to experimental inquiry. It may be trite to say that whatever subject Boys has touched he has adorned, but it is certainly true that his contributions to classical experimental physics will go down in the history of science among the highest achievements of a brilliant period.

T. O. Bergman (1735–84)

TORBERN OLOF BERGMAN was born at Katrineberg, Vestergotland, on March 10, 1735 Educated at Uppsala, he first taught mathematics and physics at the University there, before becoming professor of chemistry and mineralogy in 1767 He greatly improved upon the early technique of blowpipe and 'wet' methods of analysis His most important contribution to theoretical chemistry was his "Essay on Elective Attractions", that is, on chemical affinity For many years he endeavoured to determine the numerical values for the relative affinities of the elements, bases and acids, but his results were of little significance, since no account was taken of such factors as mass action and the volatility, insolubility, etc of some of the products of chemical reactions In the course of his investigations, Bergman discovered the elements molybdenum and tungsten, but it was said of him that "his greatest discovery was Scheele"

Medal Awards of the Institution of Chemical Engineers

AT the thirteenth annual corporate meeting of the Institution of Chemical Engineers held on February 22, the Moulton Medal, the Junior Moulton Medal and Prize of books, and the Osborne Reynolds Medal were presented. These awards wore instituted in 1929. The Moulton Medal, which commemorates the chemical engineering work of the late Lord Moulton at the Department of Explosives Supply, is in gold and bears on the obverse a portrait of Lord Moulton, and on the reverse, the seal of the Institution It is awarded for the best paper of each year presented before the Institution Papers by non members are eligible for this Medal The award for 1934 was made for a paper by Mr J Davidson Pratt and Mr G. S W Marlow, entitled "Legal Pitfalls for the Chemical Engineer" The Junior Moulton Medal is in silver, and is a duplicate of the senior award It is given for the best paper of the year read before the Graduates' and Students' Section of the Institution Only papers by graduates and students of the Institution are eligible for this Medal and Prize The 1934 award was made for the paper "Determination of the Efficiency of a Multi-Stage Washer", by Mr D Gordon Bagg The Osborne Reynolds Medal, in silver, commemorates the fundamental investigations of the late Prof Osborne Reynolds, and is the gift to the Institution of Mr F. A Greene, the honorary treasurer It bears on the obverse the seal of the Institution, and is awarded for meritorious service for the advancement of the Institution For 1934 the award was made to Mr H J Pooley, in recognition of his work as honorary director of the Appointments Bureau of the Institution since the inception of this office in 1925

New President of the Society of Chemical Industry

MR W. A. S CALDER, delegate director of the General Chemicals Group of Imperial Chemical Industries, Ltd , has been elected president of the Society of Chemical Industry for the year 1935–36. Mr. Calder's lifelong association with the chemical industry commenced after he left the Royal College of Science and joined the staff of Messrs F C Hills and Co , of Deptford In 1899 he became head chemist and manager of Messrs Chance and Hunt at Oldbury, of which firm (now part of Imperial Chemical Industries, Ltd) he became managing director in 1917 When the works were taken over by the Ministry of Munitions during the War, in addition to an increased output of acids and heavy chemicals, an important installation for the manufacture of T N T was developed under Mr Calder's direction Mr Calder is a former president of the Institution of Chemical Engineers, and has always taken an active part in the administration of that organisation and is a member of the executive board of the Chemical and Allied Employers Federation He is the co-inventor with Dr C C Fox of the Calder-Fox scrubber for the removal of liquid and solid particles from gases

Malthus Commemoration

THOMAS ROBERT MALTHUS, the economist, author of the "Essay on the Principle of Population", died a hundred years ago on December 23, 1834, and the centenary was celebrated in Cambridge on March 2 Many distinguished economists and statisticians met in King's College, along with a few biologists who came to mark the influence of Malthus upon Darwin and his 'struggle for existence'. Prof A C Pigou presided, and addresses were delivered by Mr. C R. Fay, Mr J M Keynes, and by Dr James Bonar, whose book on "Malthus and his Work", written just fifty years ago, remains our chief authority The same company met again at dinner in Jesus College, of which Malthus was undergraduate and fellow The Master, Mr Arthur Gray, spoke to the memory of Malthus, and beside him sat the one surviving kinsman of the philosopher Dr Gray coupled the toast with Dr James Bonar's name, and charmed all his hearers with a simple, intimate account of Malthus and his friends, of the influence which Malthus exercised, and the events and circumstances which influenced him Malthus became professor of political economy at Haileybury, and was the first of all professors of that science; he was one of the early members of the Political Economy Club, together with Tooke, Ricardo and James Mill, and at the very end of his life he was one of the founders of the Statistical Society Mr Gray had many interesting things to say of David Hartley the philosopher, also a member of his College, whose "Observations on Man" and other writings had great influence on the political philosophy of the latter half of the eighteenth century Malthus and Coleridge (yet another Jesus man), both born after Hartley died, were in their several ways both deeply indebted to him. Coleridge wrote of him as "Hartley, of mortal kind Wisest", and called his son after his name. Hartley Coleridge was born all but fifty years after David Hartley died, and just two years before the "Essay on Population" appeared. Samuel Taylor Coleridge and Thomas Robert Malthus died in the same year, 1834.

The Pace of Progress

IN his Rede lecture at Cambridge on March 4, Sir Daniel Hall discussed the way in which State control is tending to retard the rate of material progress based upon science, and the effect of this tendency on scientific life and thought From the re-birth of science at the Renaissance, the time-span of social and technical progress has steadily diminished The two centuries between the invention of printing and the foundation of the Royal Society, the hundred and forty years from that time to the close of the eighteenth century, the first ninety years of the nineteenth century, and the last forty years can be regarded as a series of diminishing time-spans of approximately equal material advance Material progress which formerly was spread over several generations now occurs within a single lifetime, and our social economy is correspondingly disturbed This disturbance is the greater because of the persistence of a social structure developed when agriculture was the dominant as well as the primary industry of mankind Agriculture is at present the outstanding example of an industry brought to an economic standstill because of our inability to handle the enhanced powers of production due to science The theory of over-production, however, postulates a static society and an inelastic demand, and the disturbing effect of science in the form of invention and discovery is enhanced by greater efficiency, made possible through advances in the technique of organisation

SIR DANIEL HALL suggested that the difficulty of adjusting the pace of increased production to the social structure first became apparent in agriculture, and that the failure of peasant farming to stand up to the competition of mechanised farming in America and the newer countries was the fundamental factor in determining the shift of fiscal policies in Europe from 1870 onwards The initial aim of these policies in Europe was to preserve the fundamental peasant basis of each State and to check the rate of material change The policy of national self-sufficiency pursued by such different methods, for example, as in the Irish Free State and in Italy or Germany, has essentially the same object, and commences by lowering the standard of living as the inevitable consequence of excluding imported goods In contrast to countries which are content to forego material advantages promised by scientific progress and to accept a low standard of living as the price of national unity and sufficiency, the equally isolated Russian State embraces science as the means of creating real wealth which can be shared among all its population and definitely seeks to raise the standard of living This system also presupposes a closed autocracy in which it is doubtful whether science can continue to grow or be required, and Sir Daniel suggests that the Marketing Boards now being tried in Great Britain, while an alternative to these two types of autocracy, equally eliminate individual enterprise and threaten to damp the fire of research. Science is an extinguishable response to man's inherent curiosity and its course needs to be broadened not arrested, so that science serves the majority and not merely the interests of a few

Scientific Developments and Defence Against Air Attacks

THE Under-Secretary of State for Air, Sir Philip Sassoon, announced in the House of Commons recently that a special committee has been set up to investigate the possibilities of countering air attacks by utilising recent progress in scientific invention The committee, which is already at work, consists of Mr H T Tizard, rector of the Imperial College of Science and Technology (chairman), Prof A V Hill, Foulerton research professor of the Royal Society, Prof P M S Blackett, professor of physics at Birkbeck College, University of London, and Mr H E Wimperis, Director of Scientific Research, Air Ministry It will be seen that, with the exception of the last named, the committee's composition is non-official, and Sir Philip paid tribute to the public spirit which has induced these gentlemen to give their services He also stated that while the body has been kept small to facilitate rapid progress, it is intended to invite other distinguished men of science to contribute to its investigations, and that its actual membership may be enlarged if and when it appears necessary Prof. F A Lindemann, professor of experimental philosophy in the University of Oxford, has already been invited to assist, in view of the attention that he has given to the subject It is intended to bring the committee's report before the Committee of Imperial Defence in due course

Radcliffe Telescope for University of London Observatory

OXFORD, both University and the City, is witnessing now the first results of the legal decision upholding the rights of the Radcliffe Trustees to act in the best interests of Urania This duty led them in the most obvious way possible to a happier clime, where clear skies with steady seeing occur with far more frequency than in Oxford Quite soon the quaint but beautiful Radcliffe Observatory will cease to adorn the Woodstock Road, and Pretoria will glory in its opportunity to cherish the Radcliffe 72 inch reflector now under construction at Newcastle-on-Tyne Of late, the Trustees have been engaged in finding new domiciles for such instruments as are not required in South Africa, and to this end offered to the University of London as a free gift the most valuable of the telescopes This is one of the finest examples of the skill of the late Sir Howard Grubb It comprises a photographic refractor 24 inches in diameter and 270 inches in focal length, with a visual refractor 18 inches in diameter and 270 inches in focal length The Senate of the University of London has accepted this magnificent gift for its observatory at Mill Hill, where for the last five years in a conspicuous building of attractive design an enthusiastic group has worked This notable addition to the facilities of the Observatory is a fitting reward for much labour, in that it will provide further and extended opportunities for investigation which will no doubt be fully utilised.

Birth of a Chimpanzee at the London Zoo

THE birth of a chimpanzee, at the Gardens of the Zoological Society of London on February 15, is an event worthy of record, and it shows, in no uncertain way, how carefully the well-being of the great apes is studied at the Gardens. The mother, and her daughter, we are told, are doing well. Dr. Wyatt, of St. Thomas's Hospital, and Dr. G. M. Vevers, a member of the staff of the Society, missed no opportunity of studying all the phases of pregnancy, from the time that it was detected until the birth took place. The period of gestation was 250 days. The period of labour Dr. Wyatt describes as precisely similar to that of the human being. A detailed account of the birth is to be given in the next issue of the *Proceedings* of the Society. A deficiency of calcium being suspected, the prospective mother was given regular supplies of 'Mickleffeld irradiated milk'. This is prepared by passing fresh milk, in a thin film, under ultra-violet rays, a process which results in an increase of the vitamin D content of the milk, thus making the lime salts in it more easily assimilated.

Fertility of the Earth

IN his Research and Development Lecture delivered under the auspices of the Royal Institution and the British Science Guild at the Royal Institution on March 6, Sir Frederick Keeble spoke on the fertility of the earth. Soil fertility is a product—a by-product—of the bacteria and other microscopic forms of life that teem in incredible numbers in the soil. The crops grown in field and meadow serve mankind in two ways. On one hand, they supply substance for making blood, bone, flesh and sinew and for providing energy for the work of life. On the other hand, they supply substances which stir up the body to activity so that it can use the foods for building purposes and for supplies of energy. Therefore the most important task that agricultural science can accomplish is to discover and learn to control the conditions in which soil and crop provide both the necessary body-building and energy-yielding food materials and also those that stir up growth and activity in the animal and human body. Much is known of the conditions necessary for the production of the first kinds of food. But little is known about the conditions under which crops provide the growth- and activity-provoking foods. When this is understood, foods will be judged by a new and higher standard than they are at present, and with foods conforming to that standard, human strength will increase and health will improve.

Maiden Castle, Dorchester

DR. R. E. MORTIMER WHEELER's account of his excavations at Maiden Castle, Dorchester, presented to the Society of Antiquaries of London on February 28, and his report in *The Times* of March 1, make possible a judicial estimate of the importance of this remarkable site in the prehistory of south-western Britain on more assured evidence than size alone, impressive though this may be. As Dr. Wheeler points out, Maiden Castle stands at the centre of an area noteworthy for the number of its sites of prehistoric occupation. It is clear that its history must be that of a pivotal point in cultural and social development. On the evidence afforded by the first season's exploration, four periods of occupation have been differentiated. Of these the earliest, surprisingly enough, was found to date back to the stone age—an occupation by a neolithic people, pastoralists, keeping sheep, pigs and a large breed of ox which had become extinct by historic times. They were pit dwellers and makers of pottery of the 'Windmill Hill' type. This settlement is dated tentatively at 2,000 B.C. Of the later occupations two are pre- and one late-Roman. In the early Iron Age, towards its end, possibly about the fourth century B.C., a site of about fifteen acres was enclosed by ditch, rampart and palisade. The extension of the area to its present size of about a hundred acres, with its complicated series of defences, is perhaps to be attributed to the next period of settlement, but this is not yet clear. It was in this period in the second century B.C. that peoples from Brittany, with their Celtic craftsmanship, spread over the Somerset plain, reaching Glastonbury and Meare. At Maiden Castle, however, Dr. Wheeler has as yet discerned no fundamental change in the character of the population. Towards the close of the period of Roman occupation the site, which for a time had been left derelict while the neighbouring Roman town of Dorchester was flourishing, was reoccupied and the building took place of the now famous Romano-British temple which Dr. Wheeler has rediscovered.

Kalevala Centenary

ON February 28, the Finnish people celebrated the centenary of the completion by Elias Lönnrott of the first edition of the *Kalevala*, the Finnish national folk-epic. The celebrations culminated in a great gathering in the recently completed Fair Hall at Helsingfors, at which a large number of scholars and delegates from foreign countries were present. Great Britain was represented by Mr. Robert Nichols, Dr. Margaret Murray (Royal Anthropological Institute) and Miss Agnes Dawson (Folk-Lore Society). It was at one time the fashion to compare the *Kalevala* with the Homeric poems; but in fact this great collection of the legends and folk-lore of Finland is unique in European literature, both as a picture on an enormous canvas of a very primitive stage of society and as a mosaic of pagan magic, pagan religious belief and heroic legend. In this respect it surpasses anything that can be found in the pagan element of Germanic or Scandinavian saga. It consists of a large number of ballads which Lönnrott collected among the peasantry of Karelia, the eastern province of Finland, and wove into a composite whole. It has played an important part in fostering Finnish national aspirations, and has been a fertile source of inspiration in literature, art and music. Since Lönnrott's day much further material of a similar character has been collected. The esteem in which this body of literature is held as a national possession was marked in the

present celebrations by a special session of the Diet at which a sum of approximately £9,000 was voted for the further study of the ancient history, culture and literature of the Finnish people, and by the presence of more than 4,000 people when M Mamtere, Minister of Education, opened an exhibition, at which a large collection of pictures by Gallen Kalicia, Finland's greatest painter of Kalevala subjects, was the centre of attraction

Training the Industrial Chemist

THE important subject of the training of an industrial chemist was discussed by Mr Thomas Donaldson in his address as chairman of the Glasgow Section of the Society of Chemical Industry at a meeting held jointly with the Glasgow Section of the Institute of Chemistry in the Royal Technical College, Glasgow, on March 1 Mr Donaldson is general technical manager of the Explosives Group of Imperial Chemical Industries, Ltd , and though he made it clear that he was expressing his own personal opinions, his long industrial experience and his position as a governor of the Royal Technical College give him an opportunity of forming an unbiased opinion by being able to look at the problem from both sides His chief criticism of the present system is that the training usually considered necessary to equip a man for chemical industry is too long In Scottish universities a student of chemistry takes an honours degree requiring four years study and then normally pursues research leading to a doctorate This research period extends over three years for a Ph.D and then, at the age of about twenty-four years, the man endeavours to obtain an industrial position Once in industry, it requires a further two years training before the man can be considered to be a thoroughly efficient member of his profession, since the university training has scarcely touched on industrial chemistry Mr. Donaldson suggested that instead of the present system a man should take a three years pass degree, and he could then decide whether he would continue to pursue a technical career If not, then, by two years training on the commercial side, he could become a thoroughly efficient technical salesman If he decided to remain on the technical side he had two alternatives. He could complete his honours degree and do one year's post-graduate research, or he could take a two years course in applied chemistry On this matter of starting research, Mr Donaldson said that it is far more important that students should be trained in the methods of research rather than that they should solve any particular problem

Annual General Meeting of the Institute of Chemistry

AT the fifty-seventh annual general meeting of the Institute of Chemistry held on March 1, Prof. Jocelyn Thorpe (president), in moving the adoption of the annual report, said that the register of the Institute now contains the names of 6,285 fellows and associates and more than 800 registered students. The Institute is in a strong position financially, and has co-operated with many other organisations in matters of public importance during the year Negotiations are on foot for closer co operation with other societies devoted to chemistry, particularly the Chemical Society and the Society of Chemical Industry Continuing, Prof Thorpe dealt with the importance of individualism in professional scientific life Having regard to the bearing of the subject on the development of team work in research, he emphasised especially the desirability of giving due credit to the individual worker who initiated and developed ideas He contrasted the present conditions for research work with those existing some forty years ago in the big German factories, where there was little or no intercourse between the members of the research section, who never seemed to talk to one another, being fearful lest they should communicate to their fellow-workers something of the investigations on which they had been engaged, and thus lose the credit due to themselves This competitive method has now practically died out The following were elected officers of the Institute for the ensuing year *President*, Prof Jocelyn Thorpe; *Vice-Presidents*, Mr W J A Butterfield, Sir George Clayton, Dr A E Dunstan, Mr F G Edmed, Dr H H Hodgson, Mr W H Roberts , *Hon Treasurer*, Mr P H Kirkaldy

Training in Food Technology

IN NATURE of February 23, we summarised the proceedings at a meeting held under the auspices of the Food Group of the Society of Chemical Industry, to discuss a paper on this subject by Dr. H B Cronshaw, editor of *Food Manufacture*, the *Manufacturing Chemist* (*not* the *Industrial Chemist*, as erroneously stated in the notice), the *Food Industries Weekly*, etc Dr Cronshaw writes to us to make clear that he was advocating an extension, rather than a restriction, of the food chemist's general scientific training, particularly in pre-graduate days, in the direction of physical chemistry and of biology (including bacteriology), this is not in any way inconsistent with increased technological facilities, both in teaching and in research, at the post-graduate stage He is in agreement with his fellow-members of the Food Group that the food technologist must be a scientific worker first and foremost

German Physical Congress

THE *Physikalische Zeitschrift* of December 1, 1934, contains the communications and discussions made to the German Conference of Physics held in Pyrmont last September The section on low temperatures includes reports on the magnetic method for attaining low temperatures, on supra conductivity, on the calorimetric behaviour of metals at low temperatures, on reflection of light and photo electric effect at low temperatures, etc The other section on atomic and nuclear physics includes communications on absorption lines, discharge tubes, molecular oscillations in sound-wave phenomena, positrons, cosmic particles, and electron optics, etc

European Bison in Poland

A RECENT Quarterly Information Bulletin concerning the protection of Nature in Poland records that the herd of bisons living in the forest of Bialowieza has now reached the number of fourteen individuals, of which nine belong to the pure race These are two adult males, two young males, two adult females and three young ones The remaining five are hybrids—the fourth generation of a cross between an American bison cow and a European bison bull Of the present stock, five individuals were bought in 1929, and the remainder were born in Bialowieza, as well as an additional young bull now in the zoological garden at Warsaw

Announcements

SIR LANCELOT GRAHAM, Secretary to the Government of India Legislative Department since 1924, Mr F W Ogilvie, president and vice-chancellor of the Queen's University of Belfast, and Prof G G Turner, professor of surgery in the University of London and director of the Surgical Unit at the British Postgraduate Medical School, have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

SIR GEORGE NEWMAN, who has been the chief medical officer of the Board of Education since 1907, and of the Ministry of Health since 1919, will retire on March 31 Dr. Arthur Salusbury MacNalty, a senior medical officer of the Ministry and Deputy to the Chief Medical Officer, has been appointed to succeed Sir George, and Mr Thomas Carnwath has been appointed deputy to the chief medical officer in succession to Dr MacNalty

AT the annual general meeting of the Geological Society of London held on February 15 the following officers were elected *President*, Mr J F Norman Green, *Vice Presidents*, Prof P G H. Boswell, Prof. W S Boulton, Prof H L Hawkins, Sir Thomas Holland, *Secretaries*, Prof W T Gordon, Dr. Leonard Hawkes, *Foreign Secretary*, Sir Arthur Smith Woodward; *Treasurer*, Mr F N. Ashcroft, *New Members of Council*, Mr A J Bull, Dr. R G S Hudson, Prof H H Read, Prof H H Swinnerton, Prof W W Watts

MR A. COULSTON EVANS, assistant plant pathologist at the Long Ashton Research Station, University of Bristol, has been appointed assistant entomologist at the Rothamsted Experimental Station Mr. Evans received his training at the Royal College of Science under Profs Balfour-Browne and J. W Munro; also at University College, London, under Prof. J C. Drummond, and the London School of Hygiene and Tropical Medicine under Prof. P A. Buxton. For about eighteen months, he was in France studying sheep blow-fly under Dr F G Holdaway, Council for Scientific and Industrial Research, Commonwealth of Australia, and since August 1934 has been studying fruit pests at the Long Ashton Research Station.

THE portrait of Lord Rutherford, which is Lord Bledisloe's parting gift to New Zealand, was formally presented to the trustees of the New Zealand National Art Gallery at a reception in Wellington on March 1. The Prime Minister of the Dominion as chairman accepted the gift, and in his address paid eloquent tribute to Lord Rutherford In referring to this portrait in NATURE of March 2 (p 334), it was stated that Mr Oswald Birley's original painting is in the Royal Institution This is not correct, the portrait hangs in the meeting room of the Royal Society

WRITING with reference to the article in NATURE of February 23 on "Solid Carbon Dioxide" the general manager of the Carbon Dioxide Company, Ltd, Union Marine Buildings, 11 Dale Street, Liverpool, 2, states that this firm also manufactures solid carbon dioxide, and was, indeed, the first to produce it in Great Britain on a commercial basis. The firm's trade name is 'Cardice'

THE Technical Press, Ltd, of 5 Ave Maria Lane, London, E C 4, has issued a useful classified catalogue of the technical, scientific and industrial books which it publishes The titles of technical books on practically all branches of engineering are given The firm also publishes books on trades and manufactures, arts and handicrafts, and agriculture

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A temporary assistant entomologist in the Advisory Department (Sugar Beet Pests) of the Department of Agriculture, University of Cambridge—The Secretary (March 13) A lecturer in pathology in the University of Liverpool—The George Holt Professor of Pathology (March 15) An assistant botanist in the Ceylon Rubber Research Scheme—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S W.7 (March 16) Two women lecturers in geography and in mathematics at Norwich Training College—The Principal (March 16) A principal of the Municipal College of Technology, Belfast—The Director of Education, Education Office, Victoria Street, Belfast (March 20) Two junior scientific officers at the Torry Research Station, Aberdeen—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S W 1 (March 22) Assistant laboratory worker in the Plant Pathology Departments of the Royal Horticultural Society's Laboratories at Wisley—The Director, Royal Horticultural Society, Wisley, Ripley, Surrey (March 23) A junior research officer at the Veterinary Laboratory, New Haw, Weybridge, Surrey—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S W.1 (March 25). A scientific assistant in the Imperial Bureau of Plant Genetics, School of Agriculture, Cambridge—The Deputy Director (March 31). An assistant mycologist in the Midland Agricultural College, Sutton Bonnington, Loughborough—The Acting Principal. A senior assistant engineer in the Research Department of Electric and Musical Industries, Ltd —The Employment Department.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 398

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Human Remains from Kanam and Kanjera, Kenya Colony

THANKS to facilities afforded by the Royal Society and to the courtesy of Dr L S B Leakey, I have recently had an opportunity of spending about six weeks with the East African Archaeological Expedition in the Kendu district of Kenya The chief object of my visit was to study the geology of the deposits from which the Kanam mandible and the Kanjera No 3 skull fragments were obtained, for Dr Leakey had come to the important conclusion that these remains of *Homo sapiens* type occurred *in situ* in beds of Lower Pleistocene and Middle Pleistocene age, respectively Unfortunately, it has not proved possible to find the exact site of either discovery, since the earlier expedition (of 1931–32) neither marked the localities on the ground nor recorded the sites on a map Moreover, the photograph of the site where the mandible was found, exhibited with the jaw fragment at the Royal College of Surgeons, was, through some error, that of a different locality, and the deposits (said to be clays) are in fact of entirely different rocks (volcanic agglomerate) Further confusion seems to have arisen over the photograph labelled as the horizon from which the Kanjera No 3 skull fragments were obtained, this proving to be a cliff of volcanic ash situated some distance away As the 1931–32 expedition spent three months in the area after the discovery of the mandible at Kanam (its activities being described in Dr Leakey's field-reports circulated at the time), it is regrettable that the records are not more precise

The excavations made by the 1934–35 expedition at sites which, one hoped, were close to those of the original finds, revealed the fact that the clayey beds found there had frequently suffered much disturbance by slumping The date of entombment of human remains found in such beds would be inherently doubtful, and careful investigation of the deposits by an experienced geologist at the time of discovery would therefore be essential Thus, in view of the uncertain location of the Kanam and Kanjera sites, and in view also of the doubt as to the stratigraphical horizons from which the remains were obtained and the possibility of disturbance of the beds, I hold the opinion that the geological age of the mandible and skull fragments is uncertain

It will be recalled that on March 18–19, 1933, the Royal Anthropological Institute convened a conference at Cambridge to discuss the evidence of these early human remains[1]. It would appear, from the circumstances just mentioned, that the evidence placed before the conference was unintentionally misleading. The Geological Committee at the conference prefaced its conclusion as to the stratigraphical age of the remains with the phrases "From the evidence supplied by Dr. Leakey, the Committee can see no escape from the conclusion. . . ." It seems likely that if the facts now brought forward had been available to the Committee, a different report would have been submitted

There still remains for consideration the state of mineralisation of the bones, and the succession of implements from the Kendu area The degree of mineralisation is undoubtedly high, but such a feature can be used only comparatively and with due caution[2] I am satisfied, however, that the human remains in question are much more highly mineralised than are those excavated from shell mounds in the district, believed to be Mesolithic, which are the only other human bones we have for comparison The implements actually found in undisturbed deposits in the district are not numerous, they include a few pebble tools from the Kanam area, and a few Chellian tools from the Kanjera area four miles away These occurrences appear to me to be far too meagre to constitute a succession of types similar to that at Oldoway, in Tanganyika[3]

It is disappointing, after the failure to establish any considerable geological age for Oldoway man (of *Homo sapiens* type)[4] that uncertain conditions of discovery should also force me to place Kanam and Kanjera man in a 'suspense account'

Finally, it is a pleasure to record that, during the last week of my work in the Kendu area, I had the benefit of the wide experience and sound judgment of Mr E J Wayland, director of the Geological Survey of Uganda Without committing Mr Wayland in matters of detail, I am able to say that he agrees with the main conclusions I have expressed above

P G H BOSWELL.

Cosmic Rays and Novæ

PROF W KOLHÖRSTER[1] has recently described some fluctuations in the observed intensity of cosmic rays in December last, which he suggests may possibly be connected with the appearing of Nova Herculis at that time Without venturing to judge of the reality of this particular correlation, one may inquire whether it is in general possible that nova outbursts could supply energy sufficient to maintain the supply of cosmic radiation, or a large fraction of it

Let us suppose there is an average total liberation of cosmic ray energy E in a single nova outburst The number of such outbursts in the galactic system is not known, but it has been estimated (Bailey) that there are one or two novæ per year of apparent

magnitude at maximum less than 6 The mean absolute magnitude at maximum appears to be about -5, which gives apparent magnitude 6 at 5,166 light years distance. Hence we should certainly not underestimate E if we suppose there is one nova per year at distance $r = 5{,}000$ light years, and that this one is solely responsible for the cosmic rays in our neighbourhood This would give an average energy flux $F = E/4\pi r^2 Y$ per cm ^{2} per sec outside the earth's atmosphere, where $Y = 3\ 156 \times 10^7$ sec $= 1$ year This does not imply that a nova outburst lasts on the average just one year, it gives merely an estimate of the rate of supply of cosmic ray energy if one nova appears per year at distance r Further, Regener[1] has estimated the flux of cosmic ray energy outside the atmosphere to be $3\ 53 \times 10^{-3}$ erg/cm ^{2}/sec Setting F equal to this value, we find $E \sim 3 \times 10^{49}$ ergs This should be an upper bound, and it should be safe to conclude that if a single nova is capable of liberating energy of this order, then, so far as energy considerations go, such processes could maintain the observed intensity of cosmic rays

Now Milne[2] takes a typical nova outburst to be one in which a star of initial effective temperature $T_0 \sim 8{,}000°$ collapses to a state of final effective temperature $T \sim 40{,}000°$ Also he takes the total luminosity as about the same before and after collapse, so that $R_0 T_0{}^2 = RT^2$, where R_0, R are the initial and final radii If then we take a star having initially solar dimensions, its initial negative gravitational energy is on Eddington's model $5{\cdot}66 \times 10^{48}$ ergs This quantity is inversely proportional to the radius, so that if the radius changes in the ratio $(R_0/R) = (T/T_0)^2 = 25$, then its final value is $1{\cdot}42 \times 10^{50}$ ergs. Hence the total gravitational energy liberated in the collapse is $\sim 10^{50}$ ergs This estimate was first given by Milne[4], and is independent of any theory of what happens during the actual outburst Nevertheless, he does not consider that such a large energy liberation can in fact take place, for on his stellar models the mass is much more concentrated towards the centre than in Eddington's, so the potential energy change corresponding to a given radius change is smaller Hence it appears that if stars are built on Eddington's model, then it may be possible that nova outbursts are adequate to supply the energy of cosmic rays Whether the gravitational energy is liberated in the form of cosmic rays or not, is of course another question If, however, the stars have much higher central densities, then apparently the energy supply from this source would not suffice

A more definite verdict can at present scarcely be given One needs to know more about the structure of a star just before and just after the nova phase, and more about the distribution of novæ in space In regard to the latter, it may however be pointed out that Kolhörster tentatively connects a 2 per cent increase in cosmic ray intensity with Nova Herculis Since estimates of the total number of novæ in the galaxy give 20–30 per year, he considers this fraction not unreasonable if novæ have the importance suggested However, almost all these novæ are much fainter than Nova Herculis, which should therefore make a much *larger* percentage difference.

Finally, it need scarcely be said that if the origin of cosmic rays is to be traced to novæ, then their liberation of energy in this form must vastly surpass that in the form of light For Regener's estimate gives a cosmic ray intensity almost equal to the total intensity of starlight The latter is equivalent to the light from about 2,000 first magnitude stars, while a nova rarely reaches first magnitude, and so makes but little difference to the total light intensity Actually, Unsöld has evaluated the total light emitted in a typical nova outburst as 6×10^{44} ergs, a quantity small compared with the order of 10^{49} ergs seen to be necessary for cosmic rays

Ratio of the Magnetic Moment of the Proton to the Magnetic Moment of the Deuteron

IN a previous paper[1] it was shown that it is possible to estimate the ratio of the magnetic moment of the proton to the magnetic moment of the deuteron (μ_H/μ_D) by comparing the rates of the reactions

$$\text{ortho } H_2 + O_2 \rightleftarrows \text{para-}H_2 + O_2 \qquad (1)$$

$$\text{ortho-}D_2 + O_2 \rightleftarrows \text{para-}D_2 + O_2 \qquad (2)$$

The ortho para transitions occur in the reactions (1) and (2) under the influence of the inhomogeneous magnetic field during the collisions with oxygen molecules[2]

Since the theory of the paramagnetic ortho-para-hydrogen conversion[3] has recently been investigated in some detail[4], and in addition more heavy hydrogen has become available, the ratio μ_H/μ_D has been re-determined The results obtained are given below

Temperature T (° K)	$k_{H_2}^{(2T)} / k_{D_2}^{(T)}$	μ_H/μ_D
83	12 5	3 85
193	14 5	4·03
293	14 8	4 07

$k_{H_2}^{(2T)}$ and $k_{D_2}^{(T)}$ denote the velocity constants for the reaction (1) at the temperature $2T$ and that for the reaction (2) at the temperature T respectively The ratio μ_H/μ_D is calculated according to the formula given by Kalckar and Teller[4]

$$(\mu_H/\mu_D)^2 = a\, k_{H_2}^{(2T)} / k_{D_2}^{(T)}$$

where $a = 9/8 = 1\ 12$ for $T > 120°$ K and $a = 1\ 18$ for $T = 83°$ K The variation of the ratio μ_H/μ_D with temperature is within the limits of experimental error, which is less than 5 per cent.

The present ratio is in agreement with the values for μ_H and μ_D obtained by the magnetic deflection method[5,6] It should be mentioned, however, that the ratio μ_H/μ_D as determined by the deflection method is not very certain owing to the great limit of error in the measurement of the absolute values for μ_H and μ_D

THE attempt to compress into an encyclopædia of ten volumes our present knowledge of the main facts and theories of the natural sciences is an undertaking ambitious enough to daunt even the most courageous of authors and publishers. The volumes here before us, however, cannot but be received with unstinted praise They owe their origin to the enterprise of the founder and original proprietor of the publishing house of Gustav Fischer, Jena, who felt that increasing specialisation in the sciences during the last decades had made it difficult for all except those directly connected with university institutions to keep in touch with subjects not involved in their ordinary activities. Moreover, there was the danger that science was tending to be regarded as a heterogeneous sum of unconnected spheres of knowledge and not as a harmonious whole, the *gestaltetes Wissen* which is so aptly expressed in the German word *Wissenschaft*. Our interest in the individual leaf must not extinguish our desire to see the whole tree.

Some four hundred scientific workers were therefore invited to collaborate in producing an authoritative and comprehensive work which, it was hoped, would be worthy to become the standard work of reference for the natural sciences This hope has been fully realised The second edition which lies before us is remarkably up-to-date in the information it gives Three of the original editors (H Th Simon, M Verworn, E Teichmann) have died since the appearance of the first edition, and the present editors are R Dittler (Physiology), G Joos (Physics), E Korschelt (Zoology), G Linck (Mineralogy and Zoology), F Oltmanns (Botany) and K. Schaum (Chemistry) At the beginning of each volume there is a list of contents, giving the heading and the author of each article in alphabetical order as in the actual text This preliminary index is particularly convenient for quick reference and also for finding out under what headings subjects are to be found

Chemical elements are treated in groups in accordance with the periodic classification For example, we find under the heading *Berylliumgruppe* a detailed account, covering 58 pages, of the discovery, occurrence, preparation, application, electrochemistry, analytical chemistry, thermochemistry, photo-chemistry and colloid chemistry of the elements beryllium, magnesium, calcium, strontium, barium, radium, zinc, cadmium, mercury and their compounds Many interesting observations are contained in this article; for example, that beryllium is seventeen times more transparent to X-rays than aluminium and has therefore been recommended for windows in X-ray apparatus, and that in 1927 one gram of beryllium metal cost 200 marks whereas in 1930 one kilogram cost less than 1,000 marks. It is significant that, of the four references given for beryllium, one is to the scientific publications of the *Siemens-konzern*, by whom a special issue dealing only with beryllium was issued in 1929, and one is to a publication of the Canadian Department of Mines It is doubtful whether sufficient attention has been directed in Great Britain to the great industrial possibilities of this very light metal

If we wish to refer to the atom we find four headings: *Atombau* (Estermann), *Atomkernstruktur*

(Kirsch), *Atomlehre* (Drucker), *Atom-* und *Molekular-strahlen* (Estermann) These articles occupy nearly fifty pages and, although highly condensed, contain everything of importance and much that will be new to many readers. In a set of volumes of such wide scope it is impossible to attain uniform excellence of treatment, and although the standard throughout is maintained at a high level, a certain unevenness is manifested in the number and quality of the bibliographical references In some cases references to German sources only are given, in others the most important non-German books are extensively quoted It would be a great help to the English and American reader if a little more space could be given in the next edition to the outstanding English treatises in some of the subjects A good example is set in the splendid article on the theory of elasticity (Th v Kármán) which refers to three French, four English and six German works

The subjects concerned with the different aspects of electricity occupy 383 pages in the third volume alone, there are additional articles in other volumes (for example, transformers) Concerning properties of matter there is an attractive article on surface tension (*Oberflachenspannung*) by Auerbach, copiously illustrated by diagrams taken largely from vol 7 of the "Handbuch der Mechanik". The theories of Lipmann, Helmholtz, Nernst and Krüger are briefly but lucidly described and there is also a note on electro-capillarity, the capillary telephone of Bréguet and Livén and the electro-capillary motor of Lipmann Attention may also be directed to the following among many excellent articles radiometer effects (Gerlach), northern lights (Angenheister), science of aviation (Everling), statistical physics (von Laue), stellar spectra (Siedentopf), scattering of light (Pringsheim), all of which are well illustrated.

Of the biological contributions, it may be said that, on the whole, the longer articles appear to attain a higher standard than the shorter ones More than 150 pages are devoted to the propagation of plants, no less than ten writers having contributed to the various sections We note with pleasure that Prof. F. O. Bower (Ripon, formerly of the University of Glasgow) is the author of two of these, dealing with Archegionata. Lundegårdh (Stockholm) has written the article on cyclic changes of substances in the organic world; the lengthy and elaborate article on the geography of plants is by Firbas (Göttingen) and Rikli, Rübel and Schröter, all of Zurich. An article on the nerve system seems rather old compared with most of the other contributions, very few references are to works later than 1911 and that to Sherrington bears the date 1906. The same criticism applies in a lesser degree to the article on breathing, in which J S Haldane's work is inadequately represented. These two articles might well be re-written or at any rate extended when there is a call for another edition In contrast with these, the article on the sense of touch has been excellently written and illustrated by von Skramlik (Jena). Biochemists will find a rare feast in the article on fermentation, among the contributors of which are Neuberg, Luers and Windisch Nor must we omit to mention the masterly survey given under the heading "System and Nomenclature of Chemical Substances"

Biographical notes on the life and work of eminent scientific workers of the past are also contained in these volumes, most of them have been written by Emilie Drude of Gottingen Living scientists are, rightly, not included These notes give the main essentials as regards dates and important discoveries, and also arresting details of the personal life of the savant in question We learn, for example, that Joseph von Fraunhofer, born in 1787 near Munich, was the son of a master glazier and had not yet learned to read or write when at the age of twelve he became an orphan King Max of Baden happened to have his attention directed to the boy and gave him money to buy books The youth, although entirely self-taught, became in 1818 the director of an important optical firm in Benediktbeuren, which later established itself in Munich In 1823 he was elected to the Academy of Sciences and appointed professor of physics at Munich, and a year later he was knighted His discovery of the dark lines in the solar spectrum was made in 1814; three years of further work led him to the construction of the first diffraction grating He died in 1826.

The short sketch of Johannes Kepler's life is also characterised by some personal touches. On one occasion, just after he had discovered his Third Law, he had to interrupt his work at Linz and hasten home to the help of his mother, who was in danger of being burnt as a witch. He was never free from financial worries, for his patron, Kaiser Rudolf II, rarely paid him his salary in full, and his attempts to enlist the help of Wallenstein were unsuccessful When at last he went to Ratisbon to apply to the Reichstag for the balance of his salary, he was attacked by fever and died.

The biographical notes thus reflect interesting sidelights on the private lives of the earlier men of science, and have been written with commendable taste and discrimination

The supplementary index volume (*Sachregister*) contains not only an alphabetical list of the technical references, in which the proper names and the headings of the articles are made prominent

by being printed in heavy type, but also a systematic table of the articles (with the names of their authors) under their respective headings For example, the articles dealing with botany are collected together and subdivided into nine sections, each of which contains a list of all the articles concerned with the subject-matter of that section This index and classified list considerably enhance the usefulness of the "Handworterbuch"

The volumes have been handsomely produced in the manner of Abderhalden's "Handbucher" and the numerous diagrams (more than 9,000 in the ten volumes) have been excellently drawn We are, indeed, accustomed to sets of volumes of this kind coming from Germany, a country where it appears comparatively easy to persuade scientific workers, no matter how fully occupied in routine work, to write their contributions without delay, and to find publishers who can get the volumes out in relatively few months Until the speed of working is accelerated in other countries, we are unlikely to find similar sets of handbooks on science produced in other languages

As it is desirable and in many cases even essential that these series of "Handbucher" (Physik, Experimentalphysik, Kosmische Physik, Technische Physik—to mention only the volumes on physics) should be intelligible to science students generally, the question naturally arises whether the amount of German taught in English schools meets the requirements of those who will later be engaged in scientific pursuits, whether academic or industrial No research worker can nowadays afford to be without at least a sound reading knowledge of German , and many teachers, too, would find it a boon to be able to keep in touch with the progress and methods of education in a country which has played such a pioneer part Is it too much to hope that German will soon be introduced into our schools as a compulsory subject for the great number of boys whose ultimate goal is a scientific profession ? It is true that the many translations from the German which have appeared in recent years have been a valuable aid to study in various fields, but translations rarely appear until a considerable time has elapsed after the publication of the original work, and their usefulness and freshness is therefore much reduced Moreover, in the case of research papers complete translations are, of course, out of the question

In other ways, too, the increased study of German would have its advantages in bringing the youth of England into closer contact with a great country, for which many of us have a deep and lasting affection and from which no man of science can fail to draw inspiration.

HENRY L BROSE

The Analysis of Mind

Manual Skill its Organization and Development By Dr J W Cox (Cambridge Psychological Library) Pp xx + 247 + 1 plate (Cambridge At the University Press, 1934) 16s net

IN 1904 Prof C Spearman began that long series of papers, culminating in 1927 in his book "The Abilities of Man", which gave to psychology a new method of attack upon the problem of mental constitution This method combined two techniques which were then coming into use in psychology, those of correlation and of mental testing It made possible the analysis of a concrete function such as addition It was possible to determine not only how many factors were involved but also which of them were general, that is, common to all abilities, which were group factors, that is, common to some but not all abilities, and which specific to the ability in question It was even possible to estimate the relative importance in that ability of the various factors

It was clear that only very extensive investigation could realise the full value of the Spearman method Dr J W Cox is one of those who are bringing this realisation nearer In 1928 he published what is still perhaps the best account of the investigation of a group factor ("Mechanical Aptitude" Methuen, 1928) He showed that efficiency in a 'mechanical' function, for example, the solution of an engineering problem, depends partly upon a general factor—the Spearman g or general intelligence, partly upon a factor specific to that function, and partly upon a group factor co-extensive with the field of 'mechanical' or engineering functions—the mechanical factor m From the point of view of vocational selection and guidance, the demonstration of this mechanical group factor was especially important

The present work is both a continuation of the earlier work and a breaking of fresh ground. It applies the same method to manipulative functions, chiefly to the assembling and stripping of an electrical lampholder Assembly was split into five operations which constituted five 'assembling tests'. These were used in two ways When first applied, the mode of assembly being still a problem, they were 'mechanical assembling tests' After familiarisation, they were 'routine assembling tests' The four 'stripping tests' were used only as 'routine tests'

These tests, along with tests of intelligence and of mechanical ability, were applied to groups of school children Analysis showed that the mechanical assembling tests involved the general factor g, the group factor m and specific factors,

whilst the routine assembling tests involved not only g, m and specific factors, but also a group factor especially associated with routine manual work The application of other manipulative tests showed that the manual factor was of wider scope than lampholder operations It is to be noted, however, that both m and g tend to be negligible in simple manual functions, and m in the stripping tests as well. Furthermore, whilst the manual factor is common to routine and manual assembling and to simple manual operations, it tends to disappear in favour of specific factors in operations calling for speed rather than the careful adjustment of parts, such as stripping It is clear that if the manual factor is to be measured precisely in individuals, operations of the assembling rather than the stripping type, and complex rather than simple, are called for But precise individual measurement of the manual factor is further in the future than of the mechanical factor

The demonstration of a new group factor is enough in itself to make Dr Cox's book important It contains, however, many other important findings Of these it is possible to mention only that relating to the transfer effects of practice and training

Woodrow showed in 1927 that training, that is, instruction in suitable methods of memorisation together with practice in memorising one kind of material, improves efficiency in memorising certain other kinds of material, although practice without instruction lacks this beneficial effect Dr. Cox has found not only that this is true of motor functions but also that the improvability of the functions showing transfer is increased It is to be noted, however, that the spread of the transfer thus far demonstrated is far narrower than the general transfer claimed by the old 'faculty' psychologists and some modern educationists

Research among Primitive Peoples

Essays presented to C. G Seligman. Edited by E. E. Evans-Pritchard, Raymond Firth, Bronislaw Malinowski and Isaac Schapera. Pp ix + 385 + 19 plates. (London . Kegan Paul and Co , Ltd , 1934) 21*s*. net

IT will, no doubt, be the pleasing duty of some future historian of the progress of science in the first third of the twentieth century to trace in the development of anthropological studies the influence of the Cambridge Expedition which set out for the Torres Straits in 1898 under the leadership of Dr. A. C. Haddon It was as a result of what he saw on that expedition that the late W. H. R. Rivers took up the serious pursuit of ethnology, while on the same expedition Prof. C. G Seligman, to whom this volume of essays is presented by his friends and former pupils, was inspired with that enthusiasm for research in the field among primitive peoples, which has been the dominating influence in his life-work. How much of this was due to the leader of the expedition, who contributes the foreword to this volume, it is unnecessary to inquire , but the influence, whatever its source, was decisive

Prof Seligman, as the earlier entries in the bibliography published here will show, clearly had before him a choice of distinction in more than one branch of scientific research , and his selection of anthropology as his main interest and subject of study has never been allowed to restrict unduly the play of his versatility This has given his work a flexibility and freshness of outlook, which is exemplified in his published work by his readiness to consider the bearing of advances in cognate subjects of inquiry on the methods of his own branch of investigation Thus in the wide range of topics covered by the thirty-nine contributors to this presentation volume, some perhaps almost on the fringe, rather than actually within the bounds of the science, there is none to which Prof Seligman himself has not made some more or less substantial contribution

In turn he has inspired or interested others It is in no sense invidious to suggest that much is due to his influence in, let us say, selecting almost at random, the essays by Prof. E E Evans-Pritchard on "Zande Therapeutics", the Princess Marie Bonaparte on "Psycho-Analysis and Ethnography", with its stress on the importance of the investigation of primitive peoples before it is too late, Dr Raymond Firth on "The Meaning of Dreams in Tikopia", or the "Anthropological Approach to Ethnogenics" by Capt Pitt-Rivers emphasising the practical aspects of anthropology, of which Prof Seligman has always been an ardent champion To his example too, no doubt, must be attributed Prof Malinowski's divagation to an antiquarian topic, upon which he forbears to enlarge, in a description of stone implements from eastern New Guinea

Where so much is of interest, it is difficult to select any special papers for mention. The reader's preference, whether for material culture, psychology, magic, law or religion, will scarcely fail to find satisfaction somewhere in this long list of contributions. Mr. J. Layard, for example, studies beliefs relating to the journey of the dead in the New Hebrides , Dr. G. Róheim, psycho-analytic methods in the study of character development and the ontogenetic theory of culture; Mr Henry Balfour describes the peculiar Tandu-industry of Northern Nigeria, by which an animal membrane is made into boxes and flasks; and Prof. J. L. Myres

puts forward a theory of the creation of the Tribunes of the Roman Plebs, while Dr R R Marett re-examines the old problem of food rites and their relation to totemism, sacrament and sacrifice

Even where so much is excellent or attractive, one paper stands out, not only on its intrinsic merits, but also for its critical attitude towards traditional anthropological method. This is by Dr A Hrdlička on "The Anthropological Value of the Skull" He traces the history of this character as an element in the study of man and in racial classification, and shows how it came by degrees to overshadow all other characters in the methods of physical anthropology While he does not deny that it has a real value in anthropological research, he maintains that it must be put in proper perspective and its study carried on critically Dr Hrdlička considers that the human body, including the skull, is still plastic and that great changes are going on now, for example, in the Eskimo and the American Indian The latter, indeed, has often so changed under altered conditions as to be almost worthless for type study Coming from so great, and on the whole conservative, an authority, this opinion should give pause to the too ready formulation and acceptance of racial theories

Of this volume as a whole it remains to be said that in form and contents it is worthy of its recipient, and than this there could perhaps be no higher praise The editors have earned thanks and congratulations

A Modern Naturalist

Confessions of a Scientist By Dr Raymond L Ditmars Pp xiii + 241 + 23 plates (New York: The Macmillan Co, 1934) 15s net

DR DITMARS has charge of the reptiles in the New York Zoo, but, as he tells us, he is a kind of chaperone for all its beasts, with a special liking for the more primitive and delicate forms. We tend to think we can buy everything in the way of beasts, living and dead, whereas New York seems to do much of its own collecting This means a personal knowledge on the part of its officers of the beasts in Nature, and, practically in gardens and scientifically in laboratories and museums, this is invaluable.

The assets of a keeper are observation, humour and pluck, and all these the author has to a marked degree His writings are charming and fresh, deservedly meriting their wide clientèle For pluck, read how he made a motion picture of a mamba, the quickest and most deadly of all snakes. The studio was decorated with a young hornbeam, on the spreading branches of which the mamba was induced to lie under the necessary vapour lights Here was the stimulating spring sunshine, rich in ultra-violet, that wakes the mamba—and it is surprising that the author lived to tell his tale, as the reader may see All this work and danger to secure a film! What folly? But a film may reveal movements and a play of features, unseen by the eye, and these tell us of the psychology which is as much part of a beast as his anatomy Evidently, the belief is that the film is to become part of the technique of the lecturer in zoology and to this we agree, expecting that in twenty years' time lecture rooms without cinema will be anomalies In Great Britain, the films as yet do not exist, but we look to the Zoological Society of London to give us them It is a society possessed of vision, and it has means It will soon want fresh fields to conquer, and here is one well worthy of its enterprise

To return to our text, the "Episode of the Twenty-Four Tarantulas" must be read The vampire next! She found her quarters in the Zoo, learning to feed on defibrinated blood which was diluted somewhat for her babes It required time to break her in, but films finally were secured when she approached her dish and fed Her thumb served as a foot and "there was no semblance of a bat, but a weird stalking thing, of the softest gait Bending over the dish, she darted her tongue into the sanguineous meal . . 4 darts a second Her wings spread like a flash and she hooked a hind claw overhead and was hanging, head down Gorged and inverted" More knowledge here than acquired in three hundred years of study Who would have guessed that the vampire alone among bats has the double habits of running and flight? Is there not something wrong with the scientific worker? Indeed, how many know that the range of temperature for snakes is only 32°–115° F, and that the parental care of the marmoset father for his children is to secure food for them, despite an always greedy mother

Of course, the author cannot leave the Loch Ness monster alone Who can! It was one of the biggest items in the world's news in 1933–34 and it lasted longest It is not a reptile, since there is not a reptile living that could exist in the chilly waters of the Loch—and hence it must be a warm-blooded beast, namely, a mammal Like the salmon we caught last month, it doubtless has continued to grow, and hence it might well have been a seal, which, swimming in the surface waters, produces a long wake.

Lastly, we may refer to the use of cobra venom, which has nerve toxins, for the amelioration of malignant growths. It all started with the observation that a marked improvement was shown by

a leper after being accidentally bitten by a tarantula. Then Dr Ditmars came in as a purveyor of poison, and the results are to be seen in the published accounts of the work of Dr Monae-Lesser showing that the use of cobra venom on cases of tumour, benign or malignant, always relieves pain, often stabilises the growth for a period and even in cases obtains regressions. Most snake venom, however, is of a different type, attacking the blood and destroying the red corpuscles and breaking down the walls of the blood vessels. Here injections were also tried and were found to produce a surprising effect; they inhibited the bleeding and are thus potentially of considerable use in medicine. We wonder what will come next! The last discovery was made on injecting the venom into a rabbit to make its skin more sensitive to the bleeding reaction, while the effects proved exactly the reverse.

Cytology and Genetics

Introduction to Cytology. By Lester W. Sharp. (McGraw-Hill Publications in the Agricultural and Botanical Sciences.) Third edition. Pp. xiv + 567. (New York and London: McGraw-Hill Book Co., Inc., 1934.) 30*s*. net.

THE development of cytology in its relation to genetics is a chapter of more than usual interest in the history of biology. Cytology in the modern sense developed during the last quarter of the nineteenth century as a purely observational science. The general nature and behaviour of cells, nuclei and chromosomes were worked out during that period, although the cell theory, of course, originated much earlier. The rediscovery of Mendelism and the announcement of mutation at the turn of the present century marked a new epoch in biology, and soon gave abundant meaning to the observations regarding chromosomes which the cytologists had already accumulated. Henceforth cytology and the young science of genetics mutually influenced each other, and each derived increasing strength from the observations of the other.

For a time, genetics or breeding experiments were naturally regarded as the dominant member in this remarkable partnership. But the early discovery of mutations with different chromosome numbers, of the relation between genetic linkage and the chromosomes, and of polyploidy or chromosome multiples in many plant genera, not to mention the sex chromosome mechanism in animals and its relation to sex-linked inheritance, soon made it clear that cytology would play a fundamental rôle in the future development of genetic research. Nevertheless, many geneticists were slow to realise that the cytologists had provided them with the only mechanism by which their results could be adequately explained. The practical breeders, in particular, failed to sense the necessity of calling cytology to their aid in connexion with the improvement of such important world crops as wheat and cotton, until the essential results regarding the chromosomes in these plants had been placed before them by the cytologists. This was no doubt partly because cytology requires a special equipment and an exacting technique which some investigators never fully achieve.

That geneticists now universally recognise the fundamental importance of cytology for breeding work, even in its most practical aspects, is due to the striking mass of results regarding the chromosomes and their behaviour which cytology has achieved. From being the handmaiden of genetics, cytology has become an equal partner; and to change the metaphor, it has become clear that cytology must continue to provide the foundations on which the superstructure of genetics can be built. To judge from the large proportion of genetical papers in which cytological results are reported, it might even be contended that cytology has already reached the dominant position. In a recent number of the *Journal of Genetics*, for example, six of the nine papers either reported new cytological results or were based upon cytological facts already known, while in two of the remaining three papers special facts regarding the chromosomes were involved in the interpretation. This situation is not surprising, since cytology is recognised as an essential part of the training of the younger generation of geneticists. Indeed, the term cytogenetics, now in frequent use, marks the fusion of these two sciences into one, and indicates that cytology will play an essential part in all future development of the subject. Genetics without cytology would be like the play without Hamlet.

The book before us is a useful introduction to cytology, particularly as regards plants, and much of it is devoted to the cytological foundations on which the structure of modern genetics is reared. Its usefulness is attested by the fact that it is the third edition of a work first published in 1921. Large alterations and additions have been made in the present edition, which is much improved thereby, and nearly all the relevant recent work has been included.

The work now consists of twenty-six chapters: the first seven deal with such topics as the cell, protoplasm, nucleus, plastids, Golgi material, chondriosomes and ergastic substances. The next six chapters are concerned with mitosis, chromosome structure and related subjects; the three

following, with sporogenesis, syngamy and meiosis, the phenomena in all groups of plants being compared The remaining ten chapters, except the last which gives a historical sketch of cytology, are devoted to modern work on chromosomes and heredity, chromosome fragmentation, heteroploidy, cytogenetics of hybrids and related phenomena

While there are points in which the reviewer would differ from the author in conclusions or treatment, yet it must be recognised that the work is a carefully collated and dispassionately presented account of advances in this wide field Didactic considerations have not been forgotten, and there is sufficient explanation and comparison with conditions in animal cells to make the book serviceable also to zoologists Accounts of various phenomena of general interest, such as spermatogenesis and artificial parthenogenesis in animals and endomixis in *Paramecium*, find a place The extensive references to literature have been mostly relegated to footnotes The condensed bibliography at the end runs to more than eighty pages, a feature which investigators will find of much value

The recent developments in the cytogenetics of maize, *Œnothera*, *Datura* and *Crepis* are considered at length, and the chromosome maps of *Drosophila* receive attention Evidence is presented for the new conception of the nucleolus as a body produced by a particular region of one chromosome pair The phenomena of synapsis and crossing-over are discussed, the various views being presented without dogmatic adherence to one—a very desirable feature in any work on so intricate a subject Finally, it may be mentioned that the results of microdissection work and similar studies of the living cell are incorporated.

No doubt the author will be rewarded with the appreciation of cytologists and geneticists for the production of this new and up-to-date edition, which marks the merging of these two sciences in their cognate aspects into one

R Ruggles Gates

Proper Motions of 25,000 Stars

The Radcliffe Catalogue of Proper Motions in the Selected Areas 1 to 115 Compiled by Dr H Knox-Shaw and H. G Scott Barrett. Published by Order of the Radcliffe Trustees Pp xlviii + 352 (London Oxford University Press, 1934) n p

In 1906 Kapteyn published his "Plan of Selected Areas" to bring together the various observational elements necessary for a more complete knowledge of the structure of the system of the stars To obtain data for the fainter stars (position, proper motion, magnitude, spectrum, radial velocity, and so on), he proposed that samples of 206 areas uniformly distributed over the sky should be completely investigated, and work was apportioned to different observatories Rambaut undertook the determination of the proper motions over fields of 40′ × 40′, 50′ × 50′, 60′ × 60′, depending on galactic latitude, for the 115 areas from the equator to the north pole Kapteyn's proposal was that exposures should be made sufficient to obtain stars to a definite magnitude, the plates carefully stored, and re-exposed ten years later with their centres displaced slightly This method has the disadvantage that at the second exposure, if clouds came up, the necessary limit of magnitude might not be reached The plan was modified by taking the second exposure on a separate plate, *through the glass*, and measuring the displacements by placing the plates face to face. Rambaut carried on the work from 1907 until 1923, and it has been completed under his successor's direction The difficulties attending long exposures in the climate of Great Britain are considerable, and although the aggregate exposure time on which the proper motions depend has been only 450 hours, "it has taken 24 years of unremitting effort to achieve this modest score"

The handsome volume published by the Radcliffe Trustees, compiled by Dr Knox-Shaw and Mr Barrett, gives the proper motions for 25,000 stars The average limit of magnitude is 15 2 m., only in ten fields is it below 14 5 m In addition to the proper motions, magnitudes are determined with a probable error of ±0 108 m Owing to an adjustment of the telescope in March 1914 by which the tilt of the crown and flint lenses was altered by 1′, the centre of density of the images of the brighter stars was altered relatively to that of the fainter stars, thus introducing a magnitude equation The effect of this has been successfully eliminated

The proper motions as printed are relative, as there are insufficient stars of known proper motion to serve as a zero, and it has been considered inadvisable to apply somewhat uncertain corrections for parallactic motion and solar rotation to stars of these faint magnitudes The probable errors for different areas range from ±0 0025″ to ±0 0060″ By applying the parallactic motion, the apex of the solar motion, and the vertex and axes of the Schwarzschild ellipsoid, have been found for stars 9 0–14 0 m and those fainter than 14 1 m It is pointed out that the vertex of Schwarzschild's ellipsoid is the only one of these quantities which can be satisfactorily derived from the relative motions of these faint stars

The average values of the proper motions for stars at different galactic latitudes are next given

and range from 0·010″ on the galactic equator to 0 024″ near the pole for stars of magnitude 9·0 m –14·0 m , and from 0·010″ to 0 019″ for magnitude 14·1 m –15·0 m

The stars of proper motion less than 0·1″ are collected and their distribution per square degree given for different galactic latitudes The number of variable stars found is very small, being no more than one star in 2,900.

The Radcliffe Observer and his staff are to be heartily congratulated on the conclusion of this laborious and useful piece of work

Rapid Physics

Experimental Physics a Selection of Experiments By Dr. G F C Searle Pp xiv+363 (Cambridge · At the University Press, 1934) 16*s* net

NON cuivis homini contingit adire Corinthum, and those of us who have not been fortunate enough to have come directly under the influence of Searle's inspiring personality, owe him a heavy debt of gratitude for leaving us some record—incomplete though it may be—of the methods which he has practised with such eminent success for nigh fifty years

It is an impressive record , all the more so in that this, his latest, although we hope not his last, volume shows all the vigour and energy and enthusiasm—and thank Heaven, the prejudices—that have ever characterised his work It has been called an "Odds and Ends Book", and never has there been a volume to which the term could be applied with less justification—singleness of purpose and outlook inform and penetrate every page

Skill in design , an uncanny aptitude for hitting on an experiment which will illustrate half a dozen physical principles , a remembrance of the saying that small corrections are the fun of physics , a consequent hunt for the fourth or fifth significant figure even when, Dulong-wise (or is it Petit-wise ?), the third may be now and then in doubt; the aptitude of an accomplished craftsman for making the utmost use of simple mathematics ; a violent dislike for tobacco—all the characteristics that we know and love are there.

The topics handled—do they really matter ? Still, it is usually considered to be the reviewer's first task to give his readers some inkling of the contents of the book, and we have here a record of some thirty-four experiments, four or five being devoted to dynamics, six to elasticity, thirteen to surface tension and viscosity, five to heat, and five to sound. Each of the main sections is prefaced by a chapter dealing with the mathematical principles involved.

There is but one serious criticism to put forward, and that is concerned with a section of the preface which states that the author has "abandoned a former project of writing a manual on *Experimental Electricity and Magnetism*". We trust that the author will, in the comparative leisure that will fall to him after September 30, 1935, reconsider this decision. We have heard old Triton blow his wreathèd horn, and, after revelling in the heartening blasts which he has sounded, we love not the descent to the electrical-and-magnetic bleatings of more orthodox volumes May he be persuaded to wind another strain, this time to the theme of electricity and magnetism !

Reaction Kinetics

The Reaction between Hydrogen and Oxygen By C N Hinshelwood and Dr A T Williamson. Pp v+108 (Oxford Clarendon Press , London . Oxford University Press, 1934.) 8*s* 6*d* net

WITH the rapid development of science, it is very convenient to have in one's hand from time to time a critical and authoritative up-to-date monograph on the present status of some important phases in scientific development Such an account is given by Mr Hinshelwood and Dr Williamson on the reaction between hydrogen and oxygen

The more general implications of the chain mechanism advanced by Nernst to interpret the hydrogen chlorine reaction were pointed out and developed by Semenov, who, in his famous paper of 1927 on the phosphorus - oxygen reaction, not only referred to the hydrogen - oxygen reaction, but also indicated and afterwards investigated with his collaborators the phenomena of homogeneous slow combustion, rapid combustion, degenerate and true explosions, and interpreted the phenomena of upper and lower limits of explosion. The view that such reactions are chain reactions entails an inquiry into the mechanism of the starting, propagation, reflection, branching and cessation of the chains as well as the factors operative in limiting the explosion both at the upper and lower limit These reactions form not only an important connecting link between surface or heterogeneous catalytic actions and true homogeneous reactions, but also provide us with a means for obtaining, admittedly in small concentration, new and reactive chemical entities, the chain carriers.

It is generally admitted that the hypothesis of simple atomic links such as obtain in the reactions investigated by Polanyi is not adequate to interpret the experimental data in chain reactions such

as that of hydrogen and oxygen, likewise the concept of the 'hot molecule' or energy rich molecular species such as $H_2\overset{\times}{O}$ is falling more and more into disfavour Interest is being centred more on unstable radicals which act as links and diffuse through the gas

It may be observed as first suggested by Melville that an idea as to the nature of the carrier might be obtained from its diffusion coefficient This is discussed on pp 60–61 of the present volume, in the equation given, the symbol D does not actually represent the reciprocal of the diffusion coefficient, but is only proportional to it for a given inert gas pressure Such explosive limits as are found are sometimes governed by an asymmetrical relationship between the products of the reacting gases, but this symmetry can be disturbed very considerably if the collision efficiencies for reaction of the two chain carriers are very different In this connexion it is interesting to note that there appear to be many points of similarity between the radicals of the type XH, for example, O_2H, CH_3H., CH_2 CH.H At the same time, the old idea that radiation and ionisation play an important part in the wave front of a propagated explosion appears to be entering on a new lease of life.

All those who are interested in the question of reaction kinetics must thank these authors for a well-documented monograph written with the clarity and in the style that we are accustomed to find in the communications from the Oxford laboratory E K. R

Television Systems

(1) *Television: To-day and To-morrow* By Sydney A. Moseley and H. J Barton Chapple Fourth edition Pp xxxi+208+71 plates (London: Sir Isaac Pitman and Sons, Ltd, 1934) 7*s*. 6*d* net

(2) *Television: Theory and Practice* By J. H Reyner Pp. xi+196+12 plates (London. Chapman and Hall, Ltd, 1934) 12*s* 6*d* net.

THERE is not yet a really good book in English on television. Schröter's excellent "Handbuch" was an admirable German model to which to work, although it is now happily out-of-date despite its completeness at the date of publication and its comparative youth. Neither of the present works reaches Schröter's level, although Reyner's survey is the best that has yet appeared in English

(1) Moseley and Chapple have been noticed in earlier editions; they might well have taken the opportunity offered by a fourth edition to lop off much dead wood. The main criticism even of this new edition is that it contains much more television of yesterday than of to-day or to-morrow Now that the Television Committee has administered the *coup de grâce* to that low-definition television which was an experimental triumph and an entertainment travesty, the authors would do well to condense into a brief single chapter the story of television before 1930, and to expand their treatment of the newer high-definition systems They might at the same time judiciously excise from Mr. Moseley's preface his curious reference to "the adoption of the cathode ray system after it had been practically flung on the scrap heap" Whoever flung it on the scrap heap was a singularly wrong-headed individual sinning against the light, for there has always been a very strong body of expert opinion pressing towards that cathode ray system which has now, after an unnecessary delay and at a remarkable ultimate speed, been brought to a stage the merits of which are attested by the recommendations of the Television Committee A decent veil might well be drawn, in preface and book, over this major error of judgment

The most interesting chapters of the new edition are xiii and xiv, which attempt to compress into some thirty pages the basis of cathode ray systems, the utilisation of ultra-short waves, and the intermediate-film process If the fifth edition devotes 175 pages to these subjects, and relegates to 25 pages the matter which now occupies these 175, the book will be vastly improved

(2) Mr Reyner can view the subject from a greater distance, and the improved perspective of this tele-vision results in a much better book At an epoch when even weeks are of importance in the history of the subject, it is fair to record that the author's preface is dated March, 1934 For that date the book is remarkably up-to-date, giving a whole chapter to velocity-modulation, and brief but clear accounts of the Zworykin iconoscope and the Farnsworth image dissector, important competitors in the field of true television as opposed to the more highly developed methods which may be unambiguously if inelegantly labelled 'telefilm'.

After good comprehensive surveys in the two opening chapters, the first in general terms, the second detailing the instrumental arrangements, the author passes to physiological optics in Chap. iii, to the optical elements of mechanical television systems in Chap iv, and thence to a very useful chapter on the technical characteristics of photo-electric cells In satisfactory contrast to Moseley and Chapple, Reyner then devotes three chapters to the essentials of cathode ray television These chapters may be specially commended as very fairly representative of the material published up

to the middle of 1934. Indeed this commendation may, as has already been suggested, fairly be extended to all the seventeen chapters of the book

We may hope that the author and his publishers may be moved to produce, in the next few months, a new edition including the wealth of material which is now being released as a result of the Television Committee's report Such a work would be assured of a wide circulation in the autumn, meanwhile, the present edition is a very well-balanced and accurate introduction to a subject which has now definitely climbed from mere curiosity value to real entertainment value

Progress and Economics

The Economic Consequences of Progress By Roy Glenday Pp xv+302 (London George Routledge and Sons, Ltd, 1934) 12*s* 6*d* net

THERE must be progress—even in the desert the camel is giving way to the motor-car, it is not an accident but a necessity It has far-reaching economic consequences which have proved to be unequal in their incidence on different peoples and on different strata of society Applied science is affecting the daily life of everyone to an ever-increasing degree Its supposed advantages appear sometimes to conflict with the existing state of affairs, but they are none the less real, and nothing can stop the progress of science or deprive the people of the new benefits which they are to receive by science

Nearly a hundred years ago, we in England were in the "hungry forties"—words then pregnant with real meaning of scarcity, even starvation It is stated that at the beginning of the eighteenth century, approximately one third of the population of these isles was unable to live honestly, while another third was living close to the margin of subsistence To-day there is an over-production of the essential foodstuffs which is directly due to the application of science, thus the yield of grain per acre has been increased five-fold, the average yield of milk from dairy cows is more than doubled and could be doubled again, whilst the egg yield from hens has been doubled during the last twenty-five years The world over, the price of food has fallen in consequence and the farmer is hard put to it to make a living, particularly when he is burdened with a mortgage at a high rate of interest. It is clear, moreover, that the cost of production of many foodstuffs will continue to fall. Further, the invention of cold-storage and quick long-distance transport has made the surplus food supplies of the world available in Great Britain

The standard of living, according to Sir Josiah Stamp, has increased by more than four times during the past century The economists tell us that it was not until man learned how to increase food supplies more rapidly than the rate of growth of the population that he was really able to make progress in wealth

The economic consequences of progress as we find them in 1935 are so diverse, and can be viewed from so many angles, that the business man is inclined to distrust economics as a science, and to believe that his practical experience is nearer the truth than the theories of the academic economist It may be that progress follows a series of cycles of growth and decay or, as we term them, prosperity and depression, but it should not be beyond the wit of man to flatten the curves Before this can be attempted with any possibility of success, it is obviously necessary to have a full understanding of the problems such as the book before us seeks to provide

Mr Glenday's close touch with the business community enables him to write from an angle which the business man understands In the first half of his book he traces the laws of growth and structure which have in fact controlled progress, in the second he deals with the future with a prophecy of what must be done to prevent disaster His final attitude is in effect that we should abandon the economic struggle for increasing wealth and seek happiness and cultural progress by other means, involving a largely planned civilisation and controlled population we must learn to control our numbers and their output of goods

The fundamental changes in this direction which the great combines and the men in charge of them are bringing about are stressed by Mr Glenday It is significant to find him recording that many of them "are tending less and less to regard their undertakings as mere profit-making machines for absentee shareholders and more and more to behave as the leaders of the armies of industrial advance"

The new science of 'scientific management', on which there is to be an International Congress in London this year, deals essentially with the "art of generating, utilising and controlling educational forces within industry and without, so that the human industrial team can continually be equipping itself for performing its task with a degree of efficiency ever on the upgrade". We quote this definition of management from a letter in *The Times* of January 2, 1933, signed by thirty-one leaders of industry, commerce and finance

The author has given us a readable book, erudite and enthusiastic; we commend it warmly to all interested in these problems, which concern each one of us deeply. E. F. A.

Short Notices

Archæology and Ethnology

The Annual of the British School at Athens No 32 *Session 1931–1932* Pp viii+310+42 plates (London Macmillan and Co, Ltd, 1934) 63s net

THE "Annual of the British School of Archæology at Athens" has established a reputation for a high standard of accuracy and scholarship in the presentation of the work of its members and students from year to year The present volume, which covers the session 1931–32, in this respect in no way falls short of the achievement of its predecessors These qualities indeed are the more noticeable from the fact that at present no operations of the first magnitude by the School fall to be chronicled It must not, therefore, be assumed that the contents of the present volume show any failing in interest This is far from being the case Mr N G L Hammond, for example, in his "Prehistoric Epirus and the Invasion of the Dorians", presents the archæological and historical argument in a manner as skilful as its subject is intriguing Miss Winifred Lamb's account of her excavations at Antissa have carried on a piece of work essential in duration to her previous excavations, and Mr S Benton's report on a tour of the Ionian Islands, combining a certain amount of rapid field-work with material from museum collections and other sources, would be found more than suggestive, if only money and opportunity were available for further research Among the remaining papers, Mr R P Austin reports on his excavations at Haliartos on the site of a sanctuary dating from 550 B C, Mr J D Beazley describes groups of mid-sixth century Black Figure ware and Mr R J N Jenkins some archaic Argive terra-cotta figurines The illustrations, as usual, are liberal and excellently reproduced

The Greatness and Decline of the Celts By the late Henri Hubert Edited and brought up to date by Prof Marcel Mauss, Raymond Lantier and Jean Marx Translated from the French by M R Dobie (The History of Civilization Series) Pp xvi+314 (London Kegan Paul and Co, Ltd, 1934) 16s net

IN this volume, which forms the second instalment of the late M Henri Hubert's study of the Celts, the author is no longer entirely dependent on the indirect evidence of archæology He has had at his disposal the statements of classical historians and geographers, and in the later periods a mass of material of a miscellaneous character and varying degree of authority drawn from traditions, annals and other forms of literary record. Taking the middle of the first millennium B C as his starting point, he traces the expansion of the Celts from their home in Central Europe into Italy, Spain, Gaul, the British Isles and eastward to their point of farthest penetration in the Ægean and Asia Minor. M. Hubert then follows their decline in the struggle with Rome and the Germanic peoples, until in the modern world Ireland alone remains as their sole independent and national representative in a political sense

M Hubert has reconstructed a picture of Celtic society and culture out of the reports of classical historians and geographers and the material afforded by the heroic traditions and other literary remains of the Celts themselves It suffers from the necessary limitation that it applies primarily to the Celts of Gaul and Britain only, and is not chronologically homogeneous, but the author argues with some considerable effect for its general applicability

Creation and Evolution in Primitive Cosmogonies, and other Pieces By Sir James George Frazer Pp xi+151 (London Macmillan and Co, Ltd, 1935) 8s 6d net

SIR JAMES FRAZER has here reprinted a number of 'pieces', of which the title piece of the volume is the most substantial It appeared originally in the Darwin memorial volume, published in 1909 It brings together a number of instances to show that both the concept of a special act of creation and something in the nature of the evolutionary theory are found in primitive cosmogonies Among the subsequent essays are the Zaharoff Lecture on Condorcet delivered in Oxford in 1933, biographical sketches of Sir Baldwin Spencer and the Rev John Roscoe, some reminiscences of the author's early life in Glasgow in a speech of thanks when the freedom of his native city was conferred upon him, and some memories of his parents Each of these pieces, it is scarcely necessary to say, bears the hall mark of the author's charm and finished style

Biology

The Myxomycetes a Descriptive List of the Known Species with special reference to those occurring in North America By Thomas H Macbride and G W Martin Pp x+339+21 plates (New York The Macmillan Co, 1934) 25s net

THE slime moulds are found in decaying organic matter in every country of the world, and they are probably inhabitants of all soils So far as is known, they have no economic importance and in consequence of this they are neglected Their formation of hard fructifications, in which the spores lie, gives structure upon which a classification may be based, but their systematy is of peculiar difficulty on account of an obvious responsiveness to environment while their fructifications are forming How many thousands of species of these animals or plants, whichever they be, exist in the world we do not know, but the work before us represents six years labour on the part of Dr Macbride and his research assistants. About 400 species are described in this monograph, but it occurs to us how much more

interesting and stimulating it would be, had it been preceded by a full well-illustrated account of the biology of these organisms The 573 figures, so careful for form but tiny and uncoloured, cannot tell their exquisite story and are of little use to recruit future workers, they will be the better understood if used in connexion with Arthur Lister's coloured plates in his monograph of 1911

Taxonomy is not an end in itself Indeed, it is merely a convenient method of cataloguing, and something apart from modern conceptions of science To the reviewer it is by itself analogous to stamp collecting and cataloguing - quite a good amusement but leading nowhere It becomes interesting when the stamps are studied in relation to the histories of countries, as these Myxomycetes might well be if described in relation to their environment

Insect Physiology By Dr V B Wigglesworth (Methuen's Monographs on Biological Subjects) Pp x + 134 (London Methuen and Co, Ltd, 1934) 3*s* 6*d* net

ENTOMOLOGISTS have seldom concerned themselves with problems of insect physiology The study of structure, habits and taxonomy in so vast a class has monopolised the field What is known of insect physiology has, for the most part, resulted as a side-line or by-product of other investigations, rather than as the outcome of the study of insects as such In the last ten years or so, entomologists have come to realise the necessity for exact knowledge of the functions of insect organs and tissues, especially in regard to the problems of insect control It is in the latter connexion, perhaps more than any other, that our ignorance of physiology has revealed itself most

In writing this handbook, Dr Wigglesworth imparts to his subject a freshness of outlook which only comes to a writer who has acquired first-hand knowledge His own researches into the physiological make-up of insects have broken new ground, and are always suggestive and productive of ideas The results of these studies find their place in the book but, at the same time, the author has explored the literature on insect physiology with admirable thoroughness (as the bibliography will testify) and subjected it to critical selection In a sense, the book is quite unique since it has no competitors. the only previous survey of the subject at all comparable is that of Marchal, published in 1911 It needs no further recommendation, and every entomologist and zoologist should possess it A D I.

The Familiar Trees of Hopei. By Hang-Fan Chow (Fan Memorial Institute of Biology, Peiping, Handbook No 4) Pp xiv + 370 (Peiping · The French Bookstore, 1934) Cloth, 3 dollars, paper, 2 40 dollars

THE publication of an English edition of this book simultaneously with the Chinese text will be welcome to many foreign botanists and others interested in the trees of the district around Peiping. The author claims to include only the more common species occurring in the Province of Hopei, and this object has been fully attained The Englerian system of classification is adopted. Useful keys to the families, genera and species respectively are supplied. From these, in conjunction with the descriptions, the student should in most cases have little difficulty in naming the trees met with in this part of China Taxonomic works published in China in recent years have been noted for the high standard of illustrations from line drawings, and in the present work Mr C R Feng has maintained this high standard in illustrating practically all the species which Mr Chow describes here The distribution of each species is given and under the heading "Use" are, in many cases, a number of interesting notes The book is clearly printed, but there is no index C V B M

Chemistry

Theoretische Grundlagen der organischen Chemie Von Prof Walther Huckel Band 1 Zweite Auflage Pp xii + 475 (Leipzig Akademische Verlagsgesellschaft m b H, 1934) 19 80 gold marks

A LITTLE more than three years ago the first edition of Prof W Huckel's "Theoretical Outlines of Organic Chemistry" was published (NATURE, 129, 41, 1932) and now we have the second edition of the first volume of that work

The present edition keeps generally to the original plan, but there have been minor and justifiable rearrangements Prof Huckel's critical survey of some modern work is stimulating, but stated so didactically may, and does, meet with many criticisms The really disappointing feature of the present work is the omission of references to advances in organic chemistry which have been made during the last three years; these advances have been described, if only—and necessarily—briefly in the excellent "Annual Reports of the Progress of Chemistry" published by the Chemical Society, with a reasonably full bibliography Incidentally, it is worth while recording that the cost of this new edition of Prof Huckel's book is rather more than six times the cost of any one volume of the "Annual Reports"

The appearance of finality which the written word is apt to convey is not in keeping with the publication of new editions of such works at very short intervals. Provided that the first or original edition is well planned, and this is certainly true in the case of Prof Hückel's book, it is suggested that such rapid republication is unnecessary and it is certainly to be deprecated C S G.

Conductometric Analysis · Principles, Technique, Applications By Dr Hubert T. S. Britton. (Monographs on Applied Chemistry, Vol 8) Pp. xi + 178 (London. Chapman and Hall, Ltd., 1934.) 12*s*. 6*d*. net.

THIS book is a smaller and more specialised companion to the author's volume on "Hydrogen Ions", published in the same series. After two short introductory chapters on the nature and significance of

electrical conductivity, apparatus and methods are described in chapters iii and iv. The rest of the volume is devoted to various applications of conductometric titration.

Since the author maintains that "the conductivity of solutions can often supply useful information which cannot always be easily obtained by other means", it may be anticipated that this clear and well-produced exposition of the subject will have an extensive circulation If it be maintained that the methods advocated are suitable only for "pure research", it may be recalled that exactly the same remarks were probably made about *p*H determinations some twenty years ago The determination of hydrogen ion concentration is, however, at least as frequently carried out to-day in industrial as in academic laboratories, and Dr Britton's book should do much to bring about a similar extension of use for conductometric analysis A L B

(1) *Introductory Colloid Chemistry* Pp xiv+198 15s 6d net (2) *Laboratory Manual of Colloid Chemistry* Third edition, rewritten and reset Pp xvii+229 20s net By Prof. Harry N Holmes (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1934)

THE author's introductory text fulfils its claim to be a "short, clear, yet moderately comprehensive statement of the fundamentals of colloid chemistry" In fairly brief compass he has discussed the preparation and fundamental properties of various colloid systems, coagulation, froths and films, emulsions, gels and jellies, soaps, proteins, soils and clays, adsorption and catalysis The value of the work is enhanced by a series of well-selected references

The companion laboratory volume has now reached its third edition a fact which testifies sufficiently well to its usefulness

Laboratory manual and textbook are developed on closely parallel lines, and the manual is also enriched by a large number of references to the original literature

The author has preserved his enthusiasms, and his presentation of his subject shows an admirable combination of freshness and conciseness. A F.

Engineering

Elements of Water Supply Engineering By Prof E L. Waterman. Pp. xv+302 (New York: John Wiley and Sons, Inc., London: Chapman and Hall, Ltd, 1934) 21s 6d net

THIS work is stated by its author, who is professor of sanitary engineering in the State University of Iowa, to be a textbook for students beginning their study of water supply engineering, he disclaims that it is in any sense a treatise or a handbook. He has based it on lectures which he himself delivers and it is designed to suit the particular need of his students. Viewed from this angle, the book fills a definite purpose in regard to which the author is naturally sole arbiter, and so, although the science of hydraulics is an essential element of water supply engineering, the theoretical side of the subject, with its fundamental laws, is excluded from consideration, as being adequately treated elsewhere, and, in the case of the author's students, being taken in a concurrent course

Subject to these limitations, the volume forms a very useful introductory survey of American practice in water supply In addition to the purely technical features (reservoirs, pipes, channels, intakes, pumps and pumping plant), the communal, sanitary, chemical and financial aspects of the matter are dealt with As the purview of the work is confined to the North American continent, it contains certain things which present some degree of strangeness and novelty to English engineers For example, the *per capita* consumption of water in the leading cities of the United States is startling when compared with the standards of Great Britain One wonders what it can be used for and whether there is not excessive waste Whatever be the explanation, it is certainly instructive to have the practice of other nationalities displayed for comparison and study, and English engineering students will find the book very helpful in this respect, as in others of a more general character. B C

The Blue Book 1935: the Directory and Handbook of the Electrical and Allied Industries 53rd edition Pp xxviii+1436 (London Benn Brothers, Ltd, 1935) 25s net

THE fifty-third annual edition (1935) of the electrical trades directory and handbook will prove of value to everyone who wants to have the latest information about the activities of the electrical engineering profession and industry In this edition more societies, associations and technical schools and colleges are included Many physical constants connected with industry are given, and we were interested in an instructive page on telephone transmission units. The difference between the American standard line of cable and the English standard line is clearly explained and the decibel and neper are defined Useful particulars are given about the Bureau of the International Communication Union The grid scheme of the Central Electricity Board was completed last year, and grid tariffs for the whole of Great Britain, except south Scotland and north-east England, are in operation In the manufacturing industry a fairly general and sustained improvement occurred during 1934 The output of electricity by supply undertakings increased 14 per cent compared with the previous year The use of broadcasting and telephony has also greatly increased

Wireless for the Man-in the-Moon Perhaps a Fairy Tale, Perhaps a Textbook, Perhaps Neither By Coulombus and Decibel Pp 128 (London. George Newnes, Ltd, 1934) 2s 6d net.

JOHN PERRY was wont to say that Euclid was fit reading only for the very learned This work of 'Coulombus' and 'Decibel' falls, not necessarily for the same reasons, into the same category If the man-in-the-moon is very learned he will take no

harm from the reading, and may contrive a rare wan smile, but he will learn little or nothing He will certainly wonder whether life is made notably easier by the simple device of calling an electron a duckling If, on the other hand, he is the simple soul at or to whom the "wit and humour of the book" (guaranteed by the publishers) are directed, he may be deluded into feeling that he has "unconsciously acquired a real insight into the basic principles and practice of Wireless"

Mathematics

Differential and Integral Calculus, By R Courant Translated by E F McShane Vol 1 Pp xiii + 568 (London, Glasgow and Bombay Blackie and Son, Ltd , 1934) 20*s* net

THIS volume is an English edition of the author's original work in German on the calculus which was briefly reviewed in 1928 Although the title page announces it to be a translation, yet it is much more than this Dr McShane, in co-operation with the author, has considerably modified the treatment in order to adapt the book to the needs of English and American students Among the principal divergences from the original text, this edition contains (i) a sketch of the differentiation and integration of functions of several variables, and (ii) a collection of classified examples Although the preface claims that a large number of exercises has been added, yet, compared with English textbooks, this number is somewhat small

The course is intended for those who wish to pursue the study of the calculus and its applications as beginners Much of the rigour demanded in establishing some of the more difficult fundamental theorems has therefore been taken out of the main discussion and given later in appendixes to the chapters In this way, not only is the student enabled to pass rapidly to the practical applications, but also the presentation of the subject has been greatly enhanced, for too much rigour to a beginner is undoubtedly repellent

The book is thoroughly well printed and the text is of a clarity which is not always possible in a purely literal translation F G W B

Higher Mathematics for Engineers and Physicists By Prof Ivan S Sokolnikoff and Dr Elizabeth S Sokolnikoff Pp xiii + 482 (New York and London McGraw-Hill Book Co , Inc , 1934) 24*s* net

THE text of this volume is based upon courses of lectures given annually to engineering students in the University of Wisconsin The aim of the authors is to provide a textbook which may not only appeal to students of applied science, but may also serve as a stepping-stone to more advanced mathematical treatises A wholly rigorous and purely formal presentation has therefore not been attempted, since, as the authors wisely point out, such a course of detailed analysis would tend to bewilder many practical students and thus stifle their interest in mathematics

The calculus, beginning with elliptic integrals and leading on to those ordinary and partial differential equations most frequently met with, is thoughtfully developed This is followed by some very practical chapters on vector analysis, probability and empirical formulæ, whilst the final chapter incorporates an interesting lecture on conformal representation by Dr Warren Weaver Examples are provided at the end of each chapter, and these are to be regarded as an integral part of the text, since they embody extensions and further developments of the subject matter.

A Shorter Trigonometry By W G Borchardt and the Rev A D Perrott Pp viii + 238 + xxxii + xxxi (London G Bell and Sons, Ltd , 1934) 4*s* , without Tables, 3*s* 6*d*

As the title suggests, all the trigonometry for the several school certificate examinations is here contained in a single volume The authors have divided the text into two parts the first is introductory and therefore mainly numerical, the second deals with the more formal trigonometry The whole treatment is thoroughly sound, and every chapter contains a large number of exercises which are well designed to stimulate the pupil's interest and are not too difficult

Objection might be taken to the statements on p 86, where confusion is likely to arise in identifying cosA and sinA, previously defined as ratios, with the *lengths* of OM and PM respectively In spite of this small defect, however, the book may be confidently recommended, for the authors have carried out their purpose excellently F G W B

Miscellany

Three Philosophers (Lavoisier, Priestley and Cavendish) By W R. Aykroyd Pp. xi + 227 + 8 plates (London William Heinemann (Medical Books), Ltd , 1935) 10*s* 6*d* net

THIS is a rather charmingly written study not too deep, not heavy, not coldly ordered, and humane With the central figure Lavoisier are portrayed (with sound art in passing to and fro between the characters) Priestley and Cavendish, as complements and foils Cavendish, by birth noble, by inheritance wealthy, by genius a metrical hermit , and Priestley, the very opposite in each point, in whom an intolerable fluency in doctrine was joined with the happiest success in qualitative experimenting these two men are quite indispensable to science, yet both humanly and scientifically they stand at antipodes That third indispensable, Lavoisier, was equipped with a supremely lucid and systematising brain, and he commanded much of Cavendish's type of metrical skill, coupled (for scientific purposes) with Priestley's missionary instinct *minus* its naïvety Hence, though he lacked their peculiar gifts for discovery *per se*, he was able with this triple combination of abilities to rise to a summit higher than either of theirs.

Mr Aykroyd does not hide Lavoisier's "grabbiness" (as he calls it) in adding to his considerable wealth, and in the familiar points of scientific priority But he shows well that Lavoisier toiled greatly for the material civilising of a dirty and misgoverned nation, and that this public service came to take far more of his energy and time than did his scientific researches Nevertheless in the end it failed, as they did, to save him in '94 from the inevitable fate of the ci-devant tax-farmers The latter years of Lavoisier's life are especially well told, and the mounting crises of the time, and the author's pleasant humour enlivens his sketch of Mme Lavoisier's essay in second marriage with Count Rumford

It is not to this work that chemists and physiologists would turn for authoritative history of their sciences, for that is scarcely the author's intention; but it will appeal to them, and no less to lay readers, because it shows well the diversity of the human agents through whom scientific discovery grows

IRVINE MASSON

Hutchinson's Technical and Scientific Encyclopædia Terms, Processes, Data, in Pure and Applied Science, Construction and Engineering, the Principal Manufacturing Industries, the Skilled Trades with a Working Bibliography Edited by C F Tweney and I P Shirshov In 3 vols Vol 1 *A to Direction-Finding* Pp viii + 672 (London Hutchinson and Co (Publishers), Ltd, n d) 28s

A DYSPEPTIC reviewer once grudgingly concluded his notice of a book with the words, "We have not detected any errors, but no doubt there are some" In a work of the comprehensive range of this "Encyclopædia", it is almost inevitable that there should be sins of omission or of commission, but our attitude towards such an enterprise is one of admiration for what has been so well done rather than of finding faults in it The work is, however, not so much an encyclopædia as an encyclopædic dictionary Though a fair number of the articles may rightly be described as encyclopædic in character, most of the entries are of the nature of definitions or explanatory paragraphs relating to words and terms which make up the vocabulary of science and technology

The editors, with the assistance of about eighty principal contributors, have been successful in their treatment of a very wide field, and few points appropriate to the survey have escaped notice, even if they have only recently emerged Thus, we find definitions or explanations of such subjects as bel and decibel, ascorbic acid and carotene as vitamins, Cepheid variables, and cosmic radiation We miss cytology, and though chromosphere is included we do not find chromosome, also deuterium and diplogen occur but not diplon, and dingo but not dinosaur. These, however, are but minor points, and we have no hesitation in saying that the editors and the publishers deserve the thanks of all who are engaged in scientific or industrial occupations for this handy and helpful work of ready reference We trust the two further volumes will maintain the same high standard.

Scrambles in Japan and Formosa By the Rev W H Murray Walton Pp 304 + 26 plates (London Edward Arnold and Co, 1934) 18s net

BOOKS on Formosa are relatively few, and this one treats of the little known mountainous part of that island, much of which is still only nominally under Japanese control The hill tribes were left alone by the Chinese, but are gradually being subdued by the Japanese There is a brief sketch of the habits of these 'head hunters', and a great deal about the rugged peaks of the island, including Niitaka, which rises to well over twelve thousand feet After the ascent of these and other lofty peaks, Mr Walton returned to Japan and climbed in the Japanese Alps There is an interesting chapter about the island of Yakushima and its forests and people It is, however, in respect of the attention it gives to Formosa that this book has its chief value There are useful maps and many photographs

Alpine Pilgrimage By Dr Julius Kugy Translated by H E G Tyndale Pp xxii + 374 + 20 plates (London John Murray, 1934) 12s net

IN this volume a well known mountaineer summarises the work of forty five years, mainly in the Carnic and Julian Alps It is a book that should delight not only climbers but also all who care for mountain scenery and alpine pastures, for Dr Kugy writes with equal charm of the hills, the flowers and the animal life. The technique of climbing interests him little and he claims to have written neither a climber's guide nor a book of sport Achievements, though he could claim many, do not impress him To him the charm of mountaineering lies in the solitude and beauty, and he abhors the dedication of Alpine heights to record breakers, and tourists with provisioned huts and inns and mountain railways There are many fine photographs and a useful map The book should delight all mountaineers

Philosophy and Psychology

The Family its Sociology and Social Psychiatry By Prof J K Folsom (Wiley Social Science Series) Pp xiii + 604 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1934) 25s net

THE development of modern society in the post-War period has been denounced as thoroughly immoral and degenerate, it has been justified as an expansion of the opportunity for self expression Dr Folsom studies the function of the family as an integral part of society and, without expressing an ethical judgment, diagnoses the changes in the circumstances and conditions affecting it as part of this development, according as they conduce to or hinder the proper performance of its function in a healthy community Conduct which in the ethical judgment would be regarded as immoral, that is, not in accordance with the conventions of modern civilised society, is classified as a maladjustment

Dr. Folsom has here made a very thorough study of his subject The family is examined first as a means of satisfaction for certain human needs, it is then surveyed as a working system, and the differences in the family of the savage and the civilised man are contrasted with the view of showing what the function of the family may be in differing circumstances The changes which are taking place in romantic love, courtship, sexual relations, married life, divorce, irregular unions, the relations of parents and children and so forth, are then surveyed in the light of the data which have been collected both in Europe and in the United States Much of this material is familiar in a general way, even to those who have not made a special study of the subject, but it is here set forth in convenient form and discussed quite impartially by the author A considerable part of the book is devoted to a practical application of the conclusions which the author has reached, with the view of alleviating or remedying certain of the maladjustments which experience shows now enter into the social problem.

Science and Monism By Dr W P D Wightman (History of Science Library) Pp. 416 (London George Allen and Unwin, Ltd., 1934) 15*s* net.

Dr. Wightman makes a rapid survey of philosophical speculations concerning the character of the universe as a whole from Thales to Whitehead and of their interaction with physical theory Biological theory too he takes in his stride It is a little breathless and too much of it merely summarising other people's summaries, but he is always clear and obviously has the capacity to seize on the essentials. His comments, where he allows himself any, are pertinent and pointedly expressed Where he is dealing with thinkers he understands thoroughly, as Spinoza, he is an excellent exponent and critic.

At the end, however, it is difficult to suppress certain doubts We may take monism in a loose sense as meaning no more than that there is a wholeness of things within which events happen with some recognisable order, or in other words that though we may expect some surprises we are not always being surprised. In this sense, monism has always been the principle inspiring scientific investigation and speculation But if this were all, there would be no need to write a book about it Monism evidently means more than this for Dr. Wightman, as it has for everybody, and it is doubtful whether any strict kind of monism is compatible with empirical science If the universe is really in any way compact and homogeneous, then we cannot know anything truly about any part until we know about the whole, and if we know anything at all, in principle at least, we know everything. Consequently scientific procedure, which consists in finding out about the parts without troubling about the whole, is fallacious and unnecessary, as Hegel and some of his followers appear to have thought Perhaps Dr. Wightman will next consider whether some kind of dualism or pluralism is not an essential postulate of science.

Philosophical Studies. By the late Dr. J McT. Ellis McTaggart Edited, with an Introduction, by Dr S. V. Keeling. Pp 292. (London: Edward Arnold and Co, 1934) 12*s*. 6*d*. net.

The day has gone when a book of philosophical studies, even though its author was distinguished only as a metaphysician, is to be regarded as necessarily outside the province of a scientific journal The frontiers between science and metaphysics are no longer so rigidly drawn as they were a generation ago Science may shade off into metaphysics, and metaphysics may be informed with the scientific spirit McTaggart, for example, insisted that there is only one way of getting at the truth, and that is by proving it He would have nothing to say to the doctrine that a thing must be true because we want it to be, except that such doctrine is "false and rather cowardly". There spoke the man of science, though not of physical or biological science Again, he was lucid and definite in his broad demarcation between the aims of metaphysic and of science The former is concerned with the ultimate nature of reality, the latter is also concerned with reality, but not with its ultimate nature—a definition which is something to go on with, but perhaps not to be maintained to the end

The papers collected in this volume, under the extremely able editorship of Dr Keeling, give an interesting summary of McTaggart's philosophical method and conclusions, and would serve as a good introduction to the study of his chief published works. We quite agree with the editor that the paper entitled "An Introduction to the Study of Philosophy" is an outstanding example of philosophical summarising It is well worth the careful attention of all who are interested in the borderland between science and philosophy, as well as of those whose main interest is in philosophy

Must Philosophers Disagree? and other Essays in Popular Philosophy. By Prof F. C. S Schiller Pp xi+359 (London Macmillan and Co, Ltd, 1934) 12*s* 6*d* net

The essays in this collection, like all Dr. Schiller's work, are amusing and provocative, and sometimes more than this. The three essays on William James and his work, coming from a fervent admirer, are interesting and valuable Many who do not agree with James's philosophy would yet agree with Dr. Schiller that he is one of the creative thinkers of modern times. Perhaps the most interesting part of the book are the four connected essays called "A Philosophical Survey"; the last of which is on "Man's Future on the Earth". The author makes the useful point that at any moment there are some factors making for improvement and others for deterioration; so that a survey of present conditions, with the future unknown, provides equally good arguments for optimists and pessimists. There has been progress, but not always, or in straight lines, and it is always precarious.

Your Mind and Mine an Account of Psychology for the Inquiring Layman and the Prospective Student By Dr. Raymond B Cattell Pp 314 (London, Bombay and Sydney George G Harrap and Co, Ltd, 1934) 7*s*. 6*d* net

DR. RAYMOND CATTELL, who is psychologist to the Leicester City Education Committee, provides us in "Your Mind and Mine" with a very sensible account of psychological problems of to day. The book is charmingly written, easy to read, and will appeal to those who have to read without being in possession of technical knowledge The epoch making work of Spearman and Burt receives full consideration

We doubt the wisdom of illustrating stigmata of degeneration, having stated in the text that they are practically as common in the general population as among criminals A little knowledge is indeed a dangerous thing, and the public are very quick to air their little knowledge on so many occasions

Physics

Newton and the Origin of Colours a Study of one of the Earliest Examples of Scientific Method By Michael Roberts and E R Thomas (Classics of Scientific Method) Pp viii+133+8 plates (London · G Bell and Sons, Ltd, 1934) 3*s* 6*d*. net

IT is something of a reproach to physical science that very little has heretofore been accomplished in the matter of historical teaching Chemistry, to its great benefit, has adopted another course, and systematic lectures on the history of the science have been a commonplace for generations More than ever to-day, when the foundations of physics are being laid anew, is it necessary to approach our science historically, and thus to realise something of what the builders of the older structure thought of its permanence and its value To attempt a valuation of some one portion of the whole fascinating story in anything like a compact volume is perhaps even more difficult than to tell the full tale. A full and accurate survey of the documents involved may leave one without a picture, and it is above all essential that the characters should be set against the background of their times, and that those little details—*ce superflu, si nécessaire*—should be sketched in, which make all the difference between the vivid and the dull outlook

The authors of "Newton and the Origin of Colours" must be held to have succeeded in this by no means easy task. They have told us something of Newton, of his predecessors and contemporaries—of Robert Hooke "of middling stature something crooked, pale faced, and his face but little below, but his head is lardge, his eie full and popping, but not quick, a grey eie". They have given us an outline of the state of optics in 1660, of Newton's contributions to optical science, of the controversies with Hooke and with Linus, and of the developments of optics since Newton. They have accomplished this feat in a well-written octavo of some one hundred and thirty pages. The volume is a notable contribution to an excellent series. A. F

Ions, Electrons and Ionizing Radiations By Prof J. A Crowther Sixth edition Pp xi+340+4 plates (London Edward Arnold and Co, 1934) 12*s* 6*d*. net

THIS is a sixth edition of the well known textbook so familiar to university students of physics, and in the preface the author explains the reasons for the new edition and the manner in which it differs from its predecessor

The limitations set on the subject matter are generally indicated in the title, but as Prof Crowther points out, the very rapid advances within the last few years have necessitated much rewriting and also considerable change in the balance between the older and the newer knowledge The reader familiar with an older edition will at once recognise such main sections as those on the charge on an ion, photo-electricity, X rays, and so on He will also be pleased to note new sections on neutrons, positrons, cosmic radiation, artificial disintegration and structure of the nucleus

These sections are of course written in the author's usual lucid style, and the selection of subject matter is admirably suited to his chosen scope and object, namely, the introduction of students grounded in physics to the more recent developments

In consonance with this aim, there has been no attempt to give more than general references at the end of each chapter—a wise provision which makes it easier for the student to follow up selected topics. The book cannot be said to be overloaded with theory—the subjects being treated, on the whole, in that broad manner likely to be acceptable to science students generally

Certainly the student who works through Prof Crowther's excellent book will attain to a sound general knowledge of the experimental bases of modern physics

The Physical Basis of Things By Prof John A Eldridge (International Series in Physics) Pp xiv+407 (New York and London McGraw Hill Book Co, Inc, 1934) 22*s* 6*d* net

THE author has given, in an interesting style, a vivid account of the physics of to day As he says, the book is not primarily intended for the specialist in physics but rather to give the student an appreciation of modern physics The atom takes, of course, the main position, and relativity a subsidiary one After opening with relativity, a large section on the kinetic theory of matter follows This is particularly good in showing how the statistical method runs through the whole subject. The quantum theory and its pre-spectrum applications follow The spectrum is described in more detail than any other phenomenon This is perhaps justified, but the reader will find that the style of interesting narrative has at this stage become lost in a catalogue of spectrum series, energy levels and electron spin, to be regained, however, when nuclear physics is reached Here the transformation of atoms is described, along with the discoveries of the deutron, neutron and positron In view of the importance of these discoveries, they

might have been described at greater length The new mechanics is not treated with the same wealth of detail as the earlier subjects This is reasonable, as the book is in no sense a mathematical treatise The table of relationships between the atomic and the C G S units is useful, and the student can exercise himself and at the same time revise his knowledge by working through the set of some 150 questions at the end of the book

Elementary Dynamics for Students of Science and Engineering By Dr R C Gray Pp xi+211 (London Macmillan and Co, Ltd, 1934) 5s

THIS little volume has been specially written for students beginning a university course in engineering or applied science It aims, therefore, at giving a useful introduction to the principles of applied dynamics The subject matter is divided into two main sections one dealing with the particle, and the other with rigid bodies The latter ends with a very valuable chapter on gyroscopes The whole course is not only well arranged, but also abounds in practical applications, which are clearly explained and quite interesting

The mathematical side has only been dealt with so far as is necessary in the discussion of the principles underlying applied science The author points out that no calculus has been used as few students have previously studied it The book is well supplied with suitable exercises of a practical nature, and these are chiefly arithmetical Although the mathematical treatment is slender -and not without some very faulty statements -the course is quite a good one and admirably suited to the needs of the students for whom it was written

The Kinetic Theory of Gases being a Text and Reference Book whose Purpose is to Combine the Classical Deductions with Recent Experimental Advances in a Convenient Form for Student and Investigator By Prof Leonard B Loeb Second edition Pp xx+687 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1934) 36s net

STUDENTS of the generation which fared dryly on such treatises as Watson's would scarcely recognise their subject in the new edition of Prof Loeb's treatise The classical developments are all there for the nourishment of the student of the elements, but due regard has been taken of the astonishing changes which we associate with the name of quantum mechanics At least a third of the original text has been rewritten, and the sections which deal with specific heats, with equations of state, with dielectric constants and with magnetism, have suffered radical changes

The book needs no description or recommendation to students of kinetic theory, and it is sufficient to say that, in its revised form, it amply fulfils its claim to be a "Text and Reference Book whose Purpose is to Combine the Classical Deductions with Recent Experimental Advances in a Convenient Form for Student and Investigator" A. F

Lumineszenz-Analyse im filtrierten Ultravioletten Licht ein Hilfsbuch beim Arbeiten mit den Analysen-Lampen Von Prof Dr P W Danckwortt Dritte, erweiterte Auflage, mit einem Beitrag von Dr J Eisenbrand uber "Quantitative Messungen" Pp viii+190+16 plates (Leipzig Akademische Verlagsgesellschaft m b H, 1934) 8 50 gold marks

THE first edition of Prof Danckwortt's book appeared in 1928, and the third is mainly distinguished from its predecessor by the addition of an entirely new section on the quantitative measurement of fluorescent radiation emitted by bodies when exposed to ultra-violet light, contributed by Dr J Eisenbrand, and a further list of references to original work The apparatus and technique for qualitative observations, photography, microscopy and photomicrography are fully described The excellent set of plates included in the book bears witness to the wide range of usefulness of ultra-violet light examinations, and the thousand or so references to original papers emphasise the need of a guide such as this book provides

Technology

Photo Engraving By A J Bull Pp viii+100+15 plates (London Edward Arnold and Co, 1934) 9s net

THIS is an excellent little book It has been written with the object of providing a concise but accurate account of the various methods of photo-engraving It is intended for students, for those who are in the printing trade and may be familiar with one branch it will serve to provide a general survey of their craft, and for a wider class of students it will teach the outlines of the various methods so that their own work may be more fruitful The latter group will include advertisers, commercial artists and others who must use photo-engraving as a means to their particular ends The author's experience, both as a teacher and a research worker, has enabled him to make the book a model of clarity To the general reader, not the least interesting part is the historical outline of the application of photography to printing

The Kingdom of the Camera By T Thorne Baker. Pp xvii+209+64 plates (London G Bell and Sons, Ltd., 1934) 7s. 6d net

THE applications of photography to general science and industry have now become so numerous that few people, even among those who use photography in their daily work, have any idea of the vast variety of its possibilities For many years Mr. Thorne Baker has been associated with photographic inventors and their work, moreover, he can write a good story about things he has met with in his wide experience. In this exuberant book he gives a short survey of most of the outstanding applications of photography. Profusely illustrated with good half-tone plates, it provides a very interesting, though necessarily very brief, account of the subject.

Experimental Evidence regarding the Field of the Deuteron

A METHOD for determining the field surrounding nuclei is to scatter charged particles by the nuclei in question. If the field were of the Coulomb type, the yield of nuclei projected in a given direction under the bombardment of α particles would be proportional to $1/V^4$, where V is the velocity of the incident α-particles Any deviation from the Coulomb field will manifest itself in a deviation from this relation The experiments of Chadwick and Bieler[1] have shown that such anomalous scattering is very clearly evident in collisions between α-particles and protons for α-particle velocities corresponding to ranges greater than about 2 cm

We have made similar experiments to determine the range at which anomalous scattering begins for α-particle impacts (1) with protons, (2) with deuterons Our results for protons confirm the work of Chadwick and Bieler and show detectable anomalous scattering at 1 7 cm α-particle range for head-on collisions; experiments at a greater angle showed that the anomaly occurs at a larger range but for the same distance of closest approach The yield curves for deuterons are of the same form as for protons, as suggested by Rutherford and Kempton[2], but the anomaly begins at a lower α-particle range, namely, 1·45 cm for head-on collisions

If one calculates the distance of closest approach for the two cases, taking account of the different masses of the projected particles, one finds that the deviation from the Coulomb field occurs at $4\ 6 \times 10^{-13}$ cm for protons and $3 \cdot 1 \times 10^{-13}$ cm for deuterons It is of interest that the attractive nuclear field extends farther in the case of the proton than it does in the case of the deuteron If known corresponding radii for higher elements are plotted against Z, then it is the proton which lies off the extrapolated curve, the deuteron being more nearly regular

β-Spectra of Some Radioactive Elements

WE have investigated the β spectra of radioactive elements that are obtained by bombarding chlorine, bromine and iodine with neutrons As E. Fermi, E. Amaldi, O D'Agostino, E Rasetti and E Segrè[1] have shown, in all these cases radioactive isotopes of the bombarded elements are formed

A glass tube containing beryllium and 200 millicuries of radon was used as the source of neutrons. Surrounding the source with substances rich in hydrogen[2] highly increases in the case of bromine and iodine the probability of formation of the radioactive nuclei, and in the case of chlorine gives a marked effect[3] Therefore we immersed the source, together with the sample to be irradiated, in a container filled with water

Radioactive chlorine was observed by using carbon tetrachloride, and radioactive bromine and iodine were obtained from ethyl bromide and methyl iodide, the active atoms being separated from the irradiated substance, as suggested by Szilard and Chalmers[4], in the form of a thin layer of the corresponding silver compound.

The energy distribution of the electrons emitted was measured by the magnetic analysis method with two Geiger-Muller counters already described[5] The results obtained are shown in the last two columns of the following table

Irradiated substance	Radioactive substance	Period	Limit of the spectrum	Maximum of the spectrum
Chlorine	Cl^{38}	50 min	2,050 ± 100 kv	—
Bromine	Br^{80}	30 min	2,100 ± 100 kv	~ 500 kv
Bromine	Br^{82}	6 hr	2 100 ± 100 kv	< 300 kv
Iodine	I^{128}	30 min	2,100 ± 100 kv	~ 500 kv

So far as the accuracy of our measurements goes, all the elements investigated have the same spectral limits. Furthermore, Br^{80} and I^{128} have not only the same periods and spectral limits, but also the same shape of the spectral curve, analogous to that of radium E By comparing the spectral limits obtained here with the masses of the nuclei involved in the nuclear reactions, emission of hard γ-rays is to be expected

Ionosphere Measurements during the Partial Eclipse of the Sun of February 3, 1935

PULSE measurements were made at Deal, N J, during the solar eclipse of February 3, 1935 This eclipse began at 10 28 a m and ended at 12 32 p m with a maximum effect at the ground at Deal of approximately 40 per cent magnitude at 11 30 a m. (E S T)

The critical ionisation frequencies for the E, M^1 and F_2 regions were measured on the day of the eclipse from 8 30 a m to 2 00 p m as well as on the two following days

Our results show that the eclipse was accompanied by a decrease in the maximum ionic density of 20 25 per cent in all three regions, and that the minimum ionisation occurred at or very shortly after the eclipse maximum The percentage decrease was progressively greater from the lowest to the highest region, being approximately 20 per cent for the E region, 22 per cent for the M region and 25 per cent for the F_2 region. A progressive increase of this order is to be expected from the fact that the eclipse had a magnitude of 40 per cent at the ground and approximately 43 per cent in the F_2 region (250 km over Deal) These magnitudes are in terms of the sun's diameter, which for this eclipse means an eclipsed area of 29 and 31 per cent, respectively

This decrease in ionic density may be compared to a 50-60 per cent decrease in the E region ionisation during the eclipse of August 31, 1932, when the eclipse magnitude was 95–100 per cent

A number of observers[2] who made measurements during the 1932 eclipse agreed that while there may have been an eclipse effect in the F_2 region, it could not be definitely attributed to the eclipse in view of

the variable nature of this layer on days before and after the eclipse and because the effect which was found was not coincident with the solar effect but was considerably later

The present measurements seem to give a more definite correlation between the eclipse occurrence and the time of decrease in ionic density of the F_2 region, in that the decrease began within a few minutes after the first contact, with a minimum shortly after the maximum of the eclipse and a recovery to a more or less constant higher value a few minutes after the last contact At no time during these measurements on the eclipse day or the days after was there any other variation of a comparable magnitude

It must be remembered, however, that the F_1 region is of a very variable nature and it will take many eclipses before we are absolutely sure of the effect produced upon it

These results, together with the results of the August 31, 1932, eclipse, indicate that ultra-violet light is an important ionising agency in the E, M, F_1 and F_2 regions

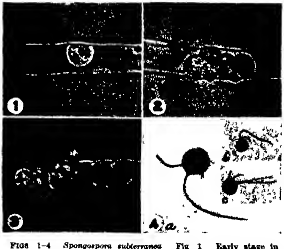
Occurrence of Zoosporangia in *Spongospora subterranea*, (Wallroth) Lagerheim

ALTHOUGH powdery scab disease of potatoes has been known and studied for nearly one hundred years, zoosporangia have never been described in the life-history of the causal organism, *Spongospora*



FIGS 1–4 *Spongospora subterranea* Fig 1 Early stage in zoosporangial formation in root hair of tomato, × 1,000 Fig 2 Zoospore discharge about to begin Note swelling on cell-wall of root hair, × 1,000 Fig 3 Zoospores being discharged, × 1,000. Fig 4 Stained zoospores, *a*, × 2,200, *b*, × 1,000, *c* (zygote ?), × 1,000.

subterranea. Zoosporangia have, however, been observed in other genera of the Plasmodiophorales by Cook[1] and by me[2] It therefore seemed probable that they might be found in *Spongospora*, especially if microscopic examinations of the roots of the host were made early in the course of the disease.

Tomato and potato seedlings were planted in soil which, after steam sterilisation, had been inoculated with spore balls from diseased tubers. At 65° F heavy infection was obtained in two weeks in the root hairs of both hosts All stages of development from amœbæ which had just penetrated the host to mature zoosporangia were observed Sometimes single zoosporangia were present in root hairs or epidermal root cells (Fig 1) More often they lay in rows or clusters (Figs 2 and 3), sometimes of a dozen or more, nearly filling the host cell Development of a single zoosporangium to form a cluster appears to take place by a process of budding

Zoospore discharge is not accomplished through exit tubes but through a rupture in the host cell-wall resulting from pressure from a swelling which develops at one point in the zoosporangium (Fig 2)

Zoospores from zoosporangia are similar to swarm-spores from germinating spore balls in size, shape, ciliation and manner of swimming It is of interest to note that the occurrence of two cilia of unequal length confirms former observations on ciliation of zoospores in the Plasmodiophorales[3] The presence of occasional binucleate spores with four cilia (Fig 4c) suggests a possible fusion of gametes Further studies are being made on the origin and subsequent development of these

An Abnormality in the *Boyau Calicial* (Female Accessory Glands) of the Desert Locust, *Schistocerca gregaria*, Forsk.

WHILE dissecting out the ovaries of the desert locust, *Schistocerca gregaria*, some time ago, I came across an abnormality in the accessory glands which is worth recording

Normally, the *boyau calicial* in *Schistocerca gregaria*, as in all other Acrididæ (vide Fedorov[1], Fenard[2] and Uvarov[3]), consist of a pair of unbranched forward prolongations of the two egg-calyces anterior to the base of the first ovariole. Each *boyau* is a much-coiled structure and usually bends inwards to touch its fellow of the other side As Fenard[2] had observed long ago, these glands acquire their maximum development shortly before oviposition and "secrete a substance which is destined to be extruded at the same time as the eggs" This substance is the material which forms the basis of the egg-pod, and also forms a protective 'froth' over the eggs In the uncoiled condition the glands are about 3 mm long in a freshly emerged female and 8–12 mm long in a female about to lay eggs.

The abnormality of the glands in the present case consists in the fact that the right gland shows an extra diverticulum arising from its outer side at a point about one third the length of the gland from its anterior tip It reaches forward beyond the latter, The length of the main gland is about 4·8 mm, and that of the diverticulum 3 mm The latter has exactly the same appearance as the main gland and

shows similar folds The left gland of this female is normal. The female in which this abnormality has been found is a young one, as is evident from the small size of the ovarioles and of the accessory glands

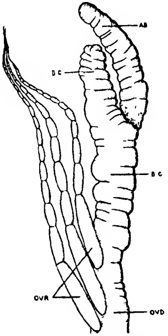

FIG 1 The right female accessory gland of *Schistocerca gregaria* Forsk, showing the abnormal outgrowth Camera lucida drawing × 12 *AB*, abnormal outgrowth of the gland *BC*, female accessory gland *OVD*, egg-calyx, *OVR*, ovarioles

I had previously dissected more than a hundred females of this species but never encountered any abnormality in the accessory glands, nor, so far as my knowledge goes, has such an abnormality been recorded in any other Acridid.

Crown Rot of Sugar Beet a Boron Deficiency

CROWN rot of sugar beet and mangel is an unsatisfactory disease to account for, and some doubt has always attended the attribution of it to the fungus *Phoma betæ*, Frank It was not entirely surprising, therefore, that Brandenburg[1] has recently shown in Holland that the disease is caused by boron deficiency, and can be cured by the addition of this element, in the entire absence of the fungus This has now been confirmed in Ireland

In the first of the present experiments, ten sugar beet seedlings were grown in Crone's solution (pH 6·2–6·5) without boron, and 20 with the addition of 1 mgm. of boric acid per litre. The former developed crown rot rapidly and to such an extent that, after 30 days, three of them were dead and seven seriously diseased, while the latter grew normally and much more vigorously. At this stage the experiment was reversed, boric acid being supplied to the seven seriously diseased plants and withheld from ten of the twenty healthy ones The effect was immediate, for the former began to grow and produced secondary crowns, as in field attacks of the disease, while the latter developed crown rot The ten plants receiving boron throughout continued to grow well to the end Similar results were obtained using Tollens' and Knop's solutions There was no parasitic fungus associated with the disease

Confirmatory results were secured in two field experiments in Carlow where the disease is very severe locally The yield and value of the crop were about doubled in one case (where the attack was exceptional) and increased by one half in the other, the sugar content being raised by 1-3 per cent, by applications of 12-20 lb of borax per acre Heavier applications did not appear to give proportionate increases, but the disease is very unevenly distributed and the optimum rate of application has not yet been determined Brandenburg used about 18 lb per acre

The discovery has much economic importance Thirty per cent of the beet area of Leinster is said to be subject to crown rot, and as a result of this work the incorporation of borax with the fertilisers is being considered The addition of borax where the disease was absent showed no apparent effect, beneficial or otherwise

Nomenclature of Vitamin B_2

PERHAPS it is useful to direct attention to the above subject before confusion gets worse confounded It was pointed out in 1931 that the use of the terms vitamin B_2 and anti-dermatitis (anti-pellagra ?) factor interchangeably was already causing difficulties[1] The discovery by Kuhn and his co-workers that lactoflavine is able to supplement a vitamin B_2-deficient diet for the growth of rats constitutes a great advance, but the anti dermatitis factor (the so-called *Haut-faktor* of the Heidelberg workers) does not appear to be identical with it Again, we have observed[2] that concentrates of renoflavine (obtained from ox-kidney extracts) have their growth-promoting effect considerably enhanced by the addition of a relatively heat- and alkali-stable substance present in ox-kidney extracts, which is not so well adsorbed by fuller's earth in acid solution as the flavine The tests were carried out with 'vitamin B' deficient rats receiving vitamins B_1 and B_4

The same heat stable factor in ox kidney extracts, which is obviously different from vitamins B_1, B_4 and the flavine, has been found also to supplement the growth-promoting power of a pure preparation of lactoflavine, very kindly supplied by Prof R Kuhn Apparently similar results obtained in biological experiments with lactoflavine have already been reported by Chick and Copping[3], and Booher, Blogett and Page[4] Elvehjem and Koehn[5] now report that flavines cannot prevent 'pellagraic' symptoms in chicks, maintained on a ration low in vitamin B_2-content That there is some factor missing in the usual vitamin B_2-deficient diet, that causes cataract in rats, is indicated by the work of Langston and Day[6]. We have ourselves met with cases of cataract

among vitamin B_2-deficient rats, but not on an extensive scale

The above would indicate in outline the complexity of what is called 'vitamin B_2.' At least four factors appear to be involved—the flavine, the heat-stable factor, the anti-dermatitis factor and the anti-cataract factor, though it is not improbable that two or more of them may be identical We would suggest that provisionally the term 'vitamin B_2' be reserved for the entire complex, which supplements the usual vitamin B_1-deficient diet for the promotion of good growth in rats The other factors may be indicated by their special characteristics or methods of assay—for example, flavine, anti dermatitis factor, anti-cataract factor, etc

We shall, perhaps, know then where we are

Reproduction and Cancer

PROF. E. C DODDS and Dr J W Cook[1] have published much information regarding the chemical and pharmacological relationship between the sex hormones such as œstrin and certain carcinogenic hydrocarbons They have established in those respects an interesting connexion between the growth changes of the uterus and those observed in certain types of cancer

There are other interesting facts concerning the two processes Thus carbon monoxide gas renders mice sterile[2], when breathed in concentrations (0·25 per cent) which do not interfere with the general growth of the body of mice acclimatised gradually ; in the same concentration the gas retards both rate of growth of mouse carcinoma No 63 (Bashford's tumour) and development of tar cancer[3]

Again, embryonic skin of mouse is—equally with placental tissue—the most potent agent in rendering mice immune to transplantable and spontaneous tumours[4], it is possible that this epithelium manufactures 'immuno bodies' as the result of œstrogenic and uterine activity The interesting question is why these 'immune bodies' should be most concentrated in the embryonic skin as compared with other embryonic tissues , it may be due to the origin of the skin from ectoderm which in the early stages lies nearest to the uterine decidua, a tissue influenced by œstrin

If œstrin is responsible, directly or indirectly, for production of natural immunity, then we should expect cancer to be most prevalent when the production of œstrin ceases. This is the case, at any rate in the female, since cancer is most prevalent after the menopause

Raman Spectrum of Gaseous Carbon Disulphide

The $\Delta\nu = 655$ cm.$^{-1}$ Raman band of carbon disulphide was photographed, the substance being in the state of vapour Fig 1 shows a spectrogram taken with a glass $F/6$ two-prism thermostated spectrograph, using a 60 cm vapour column at about 4 5 atm. pressure, irradiated by a mercury arc, the radiation from which was filtered through a dilute solution of potassium chromate to cut off the ultra-violet, avoiding photochemical decomposition and visible fluorescence of the vapour.

The exposure of the spectrogram reproduced was 100 hours on Agfa Isochrom plate, during which the 'Telex' glass Raman tube, air-freed and containing some purified carbon disulphide liquid in its tail annex, was maintained thermostatically at 100° C , the irradiated portion and the sealed-in plane-parallel window at slightly higher temperatures

FIG 1 Raman spectrum of carbon disulphide vapour Copper arc above and below

The satellites found in the spectrum of the liquid[1] and interpreted as due to transitions from excited vibrational states are not resolved, even if present, on our plates, with a linear dispersion 20 A per mm at λ4358 and a large slit width, 0 1 mm According to the most recent and accurate data for the liquid[2] the centre of gravity of the two stronger component bands is shifted by 655 0 cm^{-1} from the exciting frequency

The shift of the intensity maximum in the gaseous spectrum was observed as two Stokes lines of mercury λλ4047 and 4358, and an anti-Stokes line of the latter as marked by an arrow in Fig 1. The measured value from the two Stokes lines on the best plate (reproduced) is 655 ± 1 cm^{-1}, and is the same as the liquid shift. The negligible influence of the change of state upon the molecular vibration frequency of carbon disulphide may be expected from the smallness of dipole moment of the substance

The intensity ratio of the $\Delta\nu = 796$ cm^{-1} band to that of $\Delta\nu = 655$ cm^{-1} appears to be much lower in the spectrum of the gas than in that of the liquid. Excepting a very faint and doubtful blackening, no measurable trace of the former band has been recorded above background level up to 125 hours exposure (dotted parts in Fig 1) , whereas with the liquid, as high as 1 · 3 is reported for the above intensity ratio under ordinary conditions of observation[2]. It is intended to measure photometrically the value of it on a denser and sharper plate in the near future

Ring Method for Measuring Surface Tension

A GREAT deal has been written about the ring method since it was rescued from oblivion in 1919. It is to-day more widely used than any other throughout the world. Let us try and analyse the reasons for its success.

The first two reasons are its rapidity and facility. Whoever has laboured over any of the other methods must admit this much. The third reason was the ruggedness of the instrument—a great asset in students' laboratories and lecture rooms. The fourth reason is the reliability of the method. It was primarily intended for biological fluids, and for the first time physiologists and biological chemists could check their measurements without trouble, rapidly. It was its remarkable reliability which induced such workers as Prof. Harkins to devote much of their valuable time to establish the correction formulæ, in collaboration with Dr. Jordan, and to compute the values of the factor F for different dimensions of the ring, so as to make its readings more rigorous. A. Ferguson stated that of twenty odd methods only three were reliable: the ring method was one.

Its accuracy and reliability being established, its rapidity and ease of handling being well known, I still believe that the greatest reason for the success of the ring method was the fact that it proved to be constructive, inasmuch as it disclosed a certain number of new phenomena which were not altogether devoid of interest. I refer to the discovery that, in a solution, the establishment of equilibrium—the only conditions in which the Gibbs-Thomson thermodynamic equation is valid—is a slow process capable of being followed step by step; to the discovery of the factors governing the surface tension of protein and other solutions; of the recovery after lowering of the surface tension of such solutions by surface active substances, due to a mutual adsorption; of the existence of absolute minima; of a method for determining the surface of adsorption of materials such as charcoal, graphite, platinum black, etc.; of a method for following the process of immunity; of a photo-capillary effect in plant sap; of a method for detecting structural changes in serum proteins following inactivation; of a method for detecting alterations in transformer oil after use; of a method for ascertaining the lubricating value of oils, and so on.

Now all these phenomena do not depend on absolute but on relative values. They were found because the method was very rapid, simple, reliable, and because it was possible to take into account the time factor. Relative methods are often more fruitful than absolute ones, as absolute values are of no particular interest except when dealing with pure substances. But I think everybody will agree, particularly the biologists, that solutions offer a broader field of investigation than pure liquids. As a matter of fact, the physical chemist and the physicist use comparatively few absolute methods.

Freud and Freud, however, succeeded in developing a brilliant new theory which led them to accept the ring method as absolute, and this, in addition to the collection of new facts overlooked so far, and difficult, if not impossible, to study with another method, is another important reason why the ring method, in its modern form, has been so widely adopted in research as well as in industrial laboratories.

Oxidation of Silane

IN view of a reference by Semenoff[1] to some results recently obtained by Schantarowitsch on the upper and lower critical explosion limits in the oxidation of silane, it is of interest to record similar observations which we have made during the last six months.

We have found that pure silane when mixed with oxygen is not explosive at atmospheric pressure, but that when the pressure of the mixture is reduced, ignition occurs at a well-defined limit, which is higher the higher the temperature. The effect of two typical oxidation inhibitors (chloroform and ethyl iodide) has been examined. In small concentrations they lower the upper limit and in larger amounts prevent ignition altogether. This inhibiting action may be counteracted by increasing the temperature. Even a mixture containing the spontaneously inflammable higher hydrides of silicon may be rendered non-inflammable by small amounts of either of these inhibitors, and doubtless other substances will be found to have a similar action.

The lower oxidation limit of silane – oxygen mixtures has been examined in tubes of varying diameter, the walls of which were coated with a film of concentrated sulphuric acid. The following typical results in a cylindrical tube of 1·25 cm. diameter show the order of magnitude of this lower pressure and the relation between the pressure of the separate gases at the limit:

p_{SiH_4} (mm.)	0·837	0·605	0·368	0·272	0·241	0·198
p_{O_2} (mm.)	0·040	0·049	0·067	0·093	0·105	0·159

Under the conditions so far studied, the lower critical oxidation pressure shows a direct proportionality to a power of the vessel diameter slightly greater than unity, and not to the square of the diameter, as in the case worked out theoretically by Semenoff for deactivation on the vessel walls. On dry glass surfaces the lower limit is higher, but consistent results have not yet been obtained.

These results, which will be published in greater detail later, are in general accord with those of Schantarowitsch, as described by Semenoff, and show that the oxidation of silane resembles very closely that of phosphine rather than that of methane.

[1] "Chemical Kinetics and Chain Reactions", 1935, p. 376.

Reactivity of Carbon

X-RAY examination[1] indicates the presence of graphite in specimens of 'amorphous' carbon. Y. Oshima and Y. Fukuda[2] conclude that coke and charcoal consist of minute particles of graphite contaminated by and cemented together with hydrocarbon complexes. The so-called 'amorphous' forms of carbon generally show a chemical activity much greater than that displayed by graphite. It is, therefore, of interest to report a reaction in which the reverse is the case. During some systematic investigations of the reactivity of various types of cokes it was discovered that graded (60–100 I.M.M. mesh sieves), hard, metallurgical coke is oxidised at 100° by excess of a mixture of chromic and

phosphoric acids, much more rapidly than gas and low temperature cokes Further investigation showed that graphite and highly graphitised forms of carbon are oxidised by this mixture approximately 20–25 times more rapidly than sugar charcoal.

The following figures give the weights of carbon dioxide (the amount of carbon monoxide was negligibly small) evolved from 1·0 gm of graded samples in 2½ hours at 100°

Electrode carbon	1,043 mgm
Graphite (natural)	823 ,,
Wood charcoal	328 ,,
Metallurgical cokes	100–200 ,,
Gas cokes	87–135 ,,
Low temperature coke	75–100 ,,
Sugar charcoal	42 ,,

The anomalous position of wood charcoal in the above series is readily accounted for by its porous nature The effect of this can be reduced by fine grinding, and it was found that when more finely powdered specimens were employed the order of the above series remained the same, except in the case of wood charcoal, which fell to the position of sugar charcoal

These results indicate that, when it is possible to eliminate the effect of pore structure by employing a finely graded sample, the above reaction offers a simple method of estimating the amount of graphitised carbon in the various forms of 'amorphous' carbon

Points from Foregoing Letters

IN 1932, Dr Leakey claimed that he had discovered remains of *Homo sapiens* type *in situ* in ancient geological deposits in Kenya The deposits were older than those containing the more primitive types of man elsewhere in the world After a recent visit to the area where the remains were found, Prof P G H Boswell records that the exact sites could not be found, that errors had arisen in connexion with the photographs of the beds and that the deposits in the area had frequently been disturbed by slipping Consequently Prof Boswell regards the geological age of the remains as non-proven.

Prof Kolhorster observed an increase of 1–2 per cent in cosmic ray activity during last December, and he has suggested that it may be connected with the appearance of Nova Herculis Prof W. H. McCrea calculates the energy available when a nova is formed, that is, when (according to Prof Milne) a star collapses from a state of large volume and low temperature to one of small volume and high temperature He concludes that this energy might be sufficient to account for the cosmic rays detected, if the star is entirely gaseous previous to the collapse, as assumed by Eddington's theory, but not if the mass of the star is already concentrated towards the centre

The nuclei of ordinary and heavy hydrogen differ in several physical and chemical properties Drs L and A Farkas calculate the magnetic moment of the proton and deuteron from the rate of chemical reaction of their *para* and *ortho* varieties The value calculated agrees with that obtained by means of the more direct but less accurate method of magnetic deflection

The nuclear field of attraction of the proton extends farther than that of the deuteron, according to Mr. E Pollard and Prof H. Margenau They arrive at this conclusion from the scattering effect produced by the two nuclei upon the α-particles of radium, from which the distance of closest approach may be calculated.

The range of velocity in the electrons (β-rays) emitted by chlorine, bromine and iodine, after neutron bombardment, has been determined by Messrs. A I. Alichanow, A. I Alichanian and B S. Dželepow From mass-energy considerations, the authors are led to expect that hard γ-rays are also emitted during the nuclear reactions involved

Experiments on the reflection of radio 'pulses', made by Messrs J P Schafer and W. M. Goodall during the solar eclipse of February 3, showed a decrease in the electrical conductivity of various layers or regions of the upper atmosphere The results, though not conclusive, support the view that ultra-violet light is an important factor in producing ionisation in those regions.

E Brandenberg, in Holland, has found that the crown rot of sugar beet is due to boron deficiency, and not to a fungus disease Mr W Hughes and Prof P. A Murphy submit further experimental proof and state that the addition of 12–20 lb of borax per acre improves considerably the yield of beet in areas affected by crown rot

Dr B C Guha suggests that the term vitamin B_1 be used for the whole complex found by biological assay to be necessary to promote good growth in rats grown upon a special diet He advocates that the specific terms, anti-dermatitis factor, anti-cataract factor, etc., be used when special tests are applied involving the appearance of those diseases.

Experiments with the sex hormone (œstrin) have led to the opinion that its presence in certain circumstances may produce cancerous tissue Mr J Argyll Campbell brings forward observations suggesting that under normal conditions œstrin may be responsible for providing immunity from cancer

Dr. H J Emeléus and Mr K Stewart find that chloroform and ethyl iodide inhibit the ignition of a mixture of silane (SiH_4) and oxygen. The authors have determined the pressure at which silane becomes oxidised and find it approximately directly proportional to the diameter of the vessel used; they state that in general the oxidisation of silane resembles that of phosphine rather than that of methane.

Many instances are known in which charcoal appears to be chemically more reactive than graphite, especially when absorption is involved. Prof H L Riley and Mr. H E Blayden now find that graphite oxidises 20–25 times more rapidly with a chromic-phosphoric acid mixture, at 100°, than sugar charcoal. The reaction offers a means of estimating the amount of graphite in 'amorphous' carbon.

Research Items

Serbian Gypsies. In the course of studying the life of Serbian peasants, Mr. Alexander Petrović has collected data relating to the Serbian gypsies, and has published the first of a series of observations (*J. Gypsylore Soc.*, 3, 14, pt. 1), in which he deals with practices relating to theft. The gypsies recognise two forms of stealing, of which the first is from a Serb, when all keep silence, and the second from another gypsy, which is considered most disgraceful, and is followed by a vociferous lamentation on the part of the injured party, similar to the lamentation over the dead. It is only considered a sin to steal when what is taken is already in the house and is not needed. The gypsies perform spells for successful theft. On Christmas Eve, straw is obtained from the peasants and three twigs—of oak, beech and ash—are placed under the eaves of the house. At dusk, straw is scattered on the floor of the house and food, nuts, etc.—everything there is in the house except food containing animal fat—is placed on the table. Before supper, nuts are thrown in the four corners of the room. After the supper the housewife perambulates the house thrice, followed by the children, imitating the cries of hen and chickens. At dark all disperse to steal something in the neighbourhood, usually of no value, such as twigs or branches. Whatever is stolen is brought back and thrown in the fire, with the saying, "May it never be known what I have been stealing to-night", and then as it burns, "As this fire burns brightly, so may I steal quickly and cleverly". If a gypsy is caught in his theft, he is made fun of and not allowed to steal in the coming year.

Artificial Incubation of Pheasant Eggs. Heat and moisture are important factors in the development of birds' eggs, and the development of artificial incubation of game birds' eggs, especially in the United States, has suggested that an analysis of these factors may be of great service in reducing uncertainty in hatching and inferior quality of stock due to improper handling during incubation. The most efficient temperature for the incubation of pheasant eggs, when other physical conditions were kept constant, was 102° F. for the first period (to the end of the seventh day), 101° F. for the second period (days, 8–16), and 100° F. for the third period (up to hatching on 24th day). During the third period the incubation temperature may be considerably lowered with benefit to the embryo. As regards humidity, pheasant eggs require higher at the beginning and lower at the end of incubation, a gradient from about 75 per cent relative humidity down to about 65 per cent (Alexis L. Romanoff, Bull. 616, Cornell Univ. Agr. Exp. Stn., Ithaca, Nov. 1934). It is to be noted that temperature and moisture demands are specific, so that the needs of the quail (*Colinus virginianus*) fluctuate within a much closer range of temperature (101° F. throughout), and require a somewhat lower humidity at the beginning and higher at the end of incubation (rising from about 65–75 per cent relative humidity). The treatment of eggs of various game-birds in the same incubator is likely therefore to lead to poor results.

Australian Acarina or Mites. Mr. H. Womersley has recently published a revision of the mites belonging to the families Erythræidæ and Trombidiidæ in Australia (*Rec. South Australian Mus.*, 5, No. 2). Species of the first-mentioned family are parasites of the early stages of insects, while the Trombidiidæ are well known to be of economic importance since their larvæ are irritating pests of man. Apart from larval forms, 32 species and 2 varieties of Trombidiidæ were previously known from Australia, and 9 species of Erythræidæ. Comparatively little work has been done on this section of the fauna, only four workers having written on the subject previously. In the present paper, 46 species and 4 varieties of Trombidiidæ are listed, of which 2 genera, 14 species and one variety are new, together with two new species only known as larvæ. Of the Erythræidæ, 24 species of adults are listed, of which one genera and 14 species are new. Nine new species of larval forms of this family are described and, it may be added, no larvæ have been previously recorded from Australia. The paper is accompanied by numerous illustrations of a diagnostic character, together with a bibliography.

Ganglion Cells in the Hearts of Invertebrates. Three papers have been published by Senji Suzuki on this subject: "On the Ganglion Cells of the Heart of the Pearl Oyster *Pinctada martensi* Dunker", "On the Innervation of the Heart of Limpets" and "Ganglion Cells in the Heart of *Ligia exotica* (Roux)" (*Sci. Rep. Tôhoku Imp. Univ.*, Fourth Series (Biology) Sendai, 4, Nos. 2 and 3, 1934). Ganglion cells were found in the heart of all these animals. In the pearl oyster the heart is not traversed by the rectum, the muscles being better developed in the ventricle than in the auricle. It was found that ganglion cells were more numerous in the auricle, especially just before its junction with the ventricle. The limpets *Cellena nigrolineata* and *C. eucosmia* were alike in having the heart supplied by a nerve from the visceral ganglion and having several ganglion cells in the heart of large size and easily stainable, there being more in the ventricle than in the auricle. In the isopod *Ligia exotica*, there is a nerve fibre bundle with six ganglion cells along the dorso-median line of the heart.

Moulting and Metamorphosis in *Rhodnius*. Dr. V. B. Wigglesworth (*Quart. J. Micro. Sci.*, 77, Pt. 2, Dec. 1934) shows that in the blood sucking bug *Rhodnius prolixus* the number of moults is absolutely fixed; no departure from the normal five nymphal stages has been observed among hundreds of these insects reared in the laboratory. The five nymphal stages are more or less alike; the adult differs markedly from the nymphs. There are thus two phenomena to be considered—simple moulting and moulting coupled with metamorphosis. Moulting occurs at a definite interval after feeding, only one meal being necessary in each case. There is a 'critical period' in the moulting cycle, about 7 days after feeding in the fifth nymph, about 4 days in the earlier nymphs, and removal of the head before this period prevents moulting. Insects sharing the same blood moult simultaneously, hence the process of growth must be co-ordinated by chemical factors presumably produced by the growing cells. If fourth or even first nymphs of *Rhodnius*, decapitated soon after feeding, receive blood from moulting fifth nymphs they undergo a precocious metamorphosis and develop adult characters. Metamorphosis is therefore brought

about by chemical differences in the blood If fifth nymphs, decapitated soon after feeding, receive blood from moulting fourth nymphs, they also moult, showing that the moulting factor is the same at all stages The absence of metamorphosis in normal nymphs before the fifth stage must therefore be due to some inhibitory factor or hormone in the blood The head is necessary for the secretion of this inhibitory hormone

Cytology of Variation in Apomictic Genera. Various theories have been put forward to explain the origin of polymorphic groups of species in genera with apomictic reproduction, such as *Taraxacum*, *Hieracium* and *Antennaria* It has been supposed that they are partly sexual and have thus given rise to a swarm of forms through crossing, and it has been assumed that, even with apomictic development, gene mutations might occur which would give rise to new biotypes. In a cytological study of these conditions in *Taraxacum*, Dr A Gustafsson (*Hereditas*, **19**, 259) concludes that partial fertility does not occur in these dandelions and that new biotypes cannot be formed by the above methods He finds, however, in the megaspore mother cell, what is described as a pseudohomotypic mitosis occasionally occurring, in which the chromosomes of the heterotypic metaphase do not pair but arrange themselves in a single plane and divide It may happen that both daughter halves of a particular chromosome pass to the same pole The normal pairing of chromosomes may also lead to crossing-over. In both of those ways it is possible that new biotypes ('pseudomutations') may arise in forms which are totally apomictic The fact that in *Antennaria alpina* males arise from females although the latter are totally parthenogenetic and show various grades of intersexuality, is explained by the hypothesis that the *X* and *Y* chromosomes undergo crossing-over in prophase and may also undergo irregular distributions in the pseudohomotypic division

Fungi in the Air over Orchards When apples are gathered late in the season in several districts, they fall a prey to numerous fungi which cause unsightly 'spots' to appear during storage Horne and Nitimargi have shown that the air above an orchard contains the spores of many fungi which produce such disfiguration, whilst Mr F M Carter, of the Imperial College of Science and Technology, has recently published the results of a continuation of this work (*Trans Brit Mycol Soc*, **19**, No 2, 145–153, Jan 1935) Plates of nutrient media were exposed in orchards at East Malling, Swanley and Belfast, and the fungi which appeared were cultured and identified An extensive list of species is given, and it is rather significant that most of them are known to occur in apple 'spots'. The majority of organisms isolated from diseased apple tissue are also represented in the list Some species, such as *Sporotrichum roseum* and *Verticillium lateritium*, have not previously been obtained from diseased apples, but are shown by the present account to produce rotting when inoculated artificially Particular attention has been paid to *Pleospora herbarum*, and several new forms of the genus *Polyopeus* have been noted

A Pliocene Flora from Shansi Province. In the *Bulletin of the Geological Society of China* (**12**, No. 2; 1933) R. W. Chaney describes a flora comprising eight species from lake deposits near Taiku, Shansi Province, which have been referred to the upper Pliocene on the basis of stratigraphical relations and faunal evidence. The modern equivalents of the Taiku flora are found for the most part in the cool, semi-arid provinces of northern China, and a climate of this type appears to have characterised this part of China during the late Pliocene All the fossil species are described as new, but they show a general resemblance to the Pliocene flora of western North America The more humid and somewhat warmer type of climate indicated by the middle Tertiary floras of north-eastern Asia suggests that there has been a progressive trend towards cooling and aridity in this region since the Oligocene, which corresponds to similar climatic changes already noted in western North America during the Tertiary

Nevada Earthquake of December 20, 1932. The Cedar Mountain (Nevada) earthquake, which ranks as one of the strongest of recent earthquakes in the United States, is described in a valuable paper by Messrs V P Gianella and E Callaghan (*Amer. Seis. Soc Bull*, **24**, 345–377, 1934) Though it caused but little damage and no loss of life—the central area is thinly populated—the shock was definitely felt over an area of 400,000 square miles The principal shock occurred at 10 10 p m, Pac St Time, and its epicentre lay in lat 38° 7′ N, long 117° 8′ W One fore-shock was felt at 9 32 p m and thousands of after-shocks occurred within the next year with their epicentres lying along a belt nearly 100 miles long from north to south The most interesting feature of the earthquake was the formation of about sixty rifts in the epicentral area These rifts differ from the secondary fissures formed in alluvium with every great earthquake, for they were caused by actual shifts of adjoining rock-masses and can be traced across ridges of rock They vary in length from a few hundred feet to about four miles, and in width from less than an inch to 400 feet They occupy a belt about 38 miles long from north-west to south-east and 4 9 miles wide, and occur in a general echelon pattern With one possible exception, all are essentially vertical, and nearly all the larger rifts show a vertical displacement, usually down the slope In a few rifts, positive evidence of horizontal movement was detected, in one place amounting to 34 inches. In all of them, the east side was shifted relatively to the south, and this is also indicated by the echelon pattern of the rifts The authors notice the agreement of this direction with that during the Owen's Valley earthquake of 1872 and the Californian earthquake of 1906

Ultra-Violet Glasses. The December 1934 issue of the *Journal of Research* of the National Bureau of Standards contains a research paper on ultra violet transmission changes in glass as a function of the wave-length of the transmission stimulus, by Drs W W Coblentz and R. Stair of the Bureau. It constitutes an important addition to the series of papers which have issued from the Bureau dealing with the properties of these glasses. The object of these investigations is to determine what are the particular wave-lengths in sunlight which cause deterioration of the transmission of such glasses, for what wave-lengths this deterioration is most marked and what is the constituent of the glass which is accountable for the changes. So far, it seems the deterioration is due mainly to wave-lengths shorter than 3000×10^{-8} cm and the greatest reduction in

transparency is for wave-lengths of this type For 3050 the reduction is to about 40 per cent of the initial transparency after six weeks exposure to sunlight in May and June, and it remains near that figure for a considerable period By exposing the glass to light between λ 3300 and λ 4050, the transparency for λ 3000 light may be increased about 10 per cent As this rejuvenating light is present in sunlight, both deterioration and improvement of transparency are going on during daily exposure The overall deterioration for the whole of sunlight is to about 80–85 per cent of the transmission of freshly made glass In soda lime glasses the soda appears to be the sensitive constituent

Surface and Interfacial Tension of Mercury Recent values for the surface tension of mercury range from 400 to 500 dynes/cm, and those for the interfacial tension between mercury and water from 370 to 427 dynes/cm, the greatest disagreement existing in the values found by the sessile drop method H Brown (*J Amer Chem Soc*, **56**, 2564, 1934) has modified this method and finds that the results obtained with large flat drops and with small ones agree with those obtained with the drop weight method The interfacial tension against water was found to be 374 3 dynes/cm at 25°, and the surface tensions in dry air and in a vacuum are the same to within 0 3 per cent, namely, 473 at 25° Thermodynamic considerations show that the surface tension of mercury in a vacuum must be at least 447 at 25°, which excludes some previous values On the assumption that a mercury surface oxidises in air only in the presence of water vapour, some puzzling results can be explained, such as irreversible adsorption effects and the different results sometimes obtained with a static and a dynamic method The fact, first observed by Quincke, that water spreads on a fresh clean mercury surface, affords an excellent criterion of the cleanliness of a mercury surface

Emission Spectra of Alkali Halides H Hamada has recently discussed the emission spectra of the vapours of the chlorides, bromides and iodides of sodium and potassium (*Phil Mag*, Dec 1934) The spectra were obtained by heating the salts in the hollow cathode of a discharge tube With sodium salts, the *D* lines are intensely excited and there is a nearly continuous spectrum extending to the long wave side of these lines Near the lines some band structure is observed There is a faint apparently continuous spectrum on the short wave side of the *D* lines Similar results are obtained with the potassium salts The results are correlated with the Franck-Condon theory of molecular excitation Most of the molecules excited by electron impact go into an unstable state which dissociates into a normal halogen atom and an excited sodium atom The latter atoms emit the *D* lines. In an alternative process, however, the electronically excited molecule may be set in vibration without dissociating, and it then gives rise to the band spectrum observed

Down-coming Radio Waves. D. F Martyn and A L Green (*Proc Roy Soc*, **A**, Jan) have studied the wireless waves reflected from the upper atmosphere, using a receiving system containing a vertical wire aerial and two vertical loops at right angles Each of these aerials was connected to a separate receiver and recording galvanometer. The results obtained show that the down-coming, elliptically polarised ray is often deviated laterally out of the plane of propagation This phenomenon is probably responsible for the inconsistent results obtained by other methods in measuring the angle of incidence of down-coming waves The present method enables the authors to calculate the position of the ionospheric reflecting centres responsible for the down coming ray these centres move about rather rapidly The angles of incidence observed correspond approximately to symmetrical reflection in the ionosphere, and the polarisation of the down coming wave is normally, but not always, approximately circular

Pure Calcium Chromate When calcium chromate is prepared by mixing solutions of calcium chloride and potassium chromate, the precipitated calcium chromate is always contaminated with adsorbed potassium and chloride ions Prof J Milbauer and Dr J Doškař have now discovered a method which overcomes this difficulty and have published their results in the *Proceedings of the Masaryk Academy of Work* at Prague These authors have worked out the exact conditions for the precipitation of calcium chromate by mixing solutions of calcium chloride and sodium chromate The best results were obtained by adding a solution containing 400–450 gm of calcium chloride per litre to a saturated solution of sodium chromate so that the former was in excess, namely, 1 6 times the amount required according to the equation

$$Na_2CrO_4 + CaCl_2 = 2\,NaCl + CaCrO_4$$

The best temperature for the reaction was between the limits 18° and 27° C The precipitate of calcium chromate so obtained was readily freed from any adhering salt or excess of calcium chloride, and is said to be particularly pure

Fatigue Research and Engine Design The failure of revolving shafts in engines and machinery has occurred so frequently that it has led to much investigation Ships have been lost through the breakage of propeller shafts and many motorists have been delayed by the fracture of rear axles In a booklet published by the Society of Motor Manufacturers and Traders in 1932, it was stated that, of all the breakdowns in motor-vehicles, the breaking of rear-axle shafts accounted for 13 6 per cent In most cases such failures result in nothing but expense and delay, but when shafts in ships break, the consequences may be disastrous Ever since the screw propeller was adopted, shafts have broken, anything that can explain the causes is of value to the designer A good deal of light is thrown upon the subject in a paper read on January 25 to the North East Coast Institution of Engineers and Shipbuilders entitled "The Relation of Fatigue to Modern Engine Design" In this paper, Mr R A Macgregor treated it from the aspect of the manufacturer of steel forgings, Mr. W S Burn dealt with it as an engine designer while Prof F Bacon referred to some results of researches in the laboratory. In Mr Burn's view, researches on fatigue endurance by scientific engineers were "sufficient to prove that it can be rendered quite a harmless germ if the correct antidote is administered The antidote is simply the avoidance of stress concentration or notch effect" He gave some interesting examples of the improvements effected in engine parts by the application of this maxim. The paper contains a bibliography of more than two hundred books and papers published on the subject of fatigue in this and other countries

Measurement of Geological Time*

THE report of the Committee on the Measurement of Geologic Time for the year ending April 28, 1934, prepared by the chairman, Prof A C Lane, contains an imposing record of the progress achieved and gives some account of the varied and far-reaching character of the researches now being carried out Prof Lane contributes an article dealing with the history of the subject He also directs attention to his proposal that the isotopes of uranium from which the various series originate should be distinguished as Ur-radium, Ur-actinium, Ur thorium and (if needed) Ur-virginium

The more important of the new age determinations are listed in the accompanying table All are calculated from lead ratios except those for the Triassic and Keweenawan basalts, which are based on helium determinations. As helium is liable to escape, the highest figure for the Keweenawan is most likely to be correct. From the radium contents of the travertine deposits of the Mammoth Hot Springs, Yellowstone Park, H Schlundt finds various ages up to 14,000 years A purely geological method is applied by F J Pack to the measurement of post-Miocene time. He has determined the rate of recession of the wall of Bryce Canyon at two feet per century. The wall has receded a hundred miles since the Miocene, corresponding to a period of the order 26 million years This corresponds well with the age of 28 million years found for the Cleveland Dyke in Co Durham

Geological Age	Material and Locality	Investigators	Age in Millions of Years
Triassic	Basalt, New Haven	W D Urry	170
Permian	Pitchblende, Wölsendorf	F Hecht and Edith Kroupa	205
Permian	Thorite, Langesundfjord	A von Grosse	226
Devonian	Uraninite, Glastonbury	C N Fenner	298
Late Ordovician	Uraninite, Fitchburg	F Hecht and Edith Kroupa	336
Late Cambrian	Kolm, Sweden	W R Bennett	444
Keweenawan	Basalt, Calumet and Hecla	W D Urry	302 610
Pre-Witwatersrand	Uraninite, Gordonia	A Holmes and F Hecht	925
Laurentian	Uraninite, Quebec	H V Ellsworth	1040
Pre-Laurentian	Pitchblende, Great Bear Lake	J P Marble	1260
Pre Laurentian	Monazite, Manitoba	Edith Kroupa	1725

New methods for the determination of radium have been devised by R D Evans and for thorium by W D Urry Work on the actinium series has been carried out by A von Grosse and A E Ruark A F Kovarik has found that the half-period of thorium is close to 1 3 × 10^{10} years, a result that agrees with independent measurements by Heimann and by Fesefeldt and confirms the value adopted by Kovarik and Holmes in the "Age of the Earth" (*Bull* 80, Nat Res Coun , 1931) Determinations of the atomic weight of lead from radioactive minerals have been made by O Honigschmid, J P Marble, C M Alter and A D Bliss

The extremely sensitive magneto optic methods of F Allison have now been brought into use C S Piggot, of the Geophysical Laboratory, has co operated with Allison in detecting the isotopes of lead in various minerals, particularly those of the Great Bear Lake pitchblende deposits Sixteen isotopes of lead are now known and eight of uranium The programme of research on the disintegration of potassium and the accumulation of Ca^{41} in rocks and minerals during geological time, announced by Holmes at the York meeting of the British Association, is being carried out systematically in collaboration with Allison, who has so far determined Ca^{41} in about a hundred analysed materials The results, which it is hoped will soon be published, not only throw much-needed light on the vexed question of the origin of igneous rocks, but also serve in the case of appropriate rocks and minerals to determine the period at which consolidation took place

Prof Lane and his Committee and the active team of associated workers are to be congratulated on the spectacular acceleration of progress that the last few years have witnessed

* National Research Council Division of Geology and Geography Report of the Committee on the Measurement of Geologic Time, presented at the Annual Meeting of the Division of Geology and Geography, National Research Council, April 28, 1934 Pp ii+86 (Washington, D C National Research Council, 1934)

The Pre-Crag People of Suffolk

ON February 19, Mr Reid Moir spoke at the Royal Anthropological Institute on "The Age of the Sub Crag Flint Implements". It is now twenty-five years since the first traces of man were found in the Suffolk Bone Bed beneath the Red Crag The Bone Bed is of very considerable geological antiquity, and predates those deposits containing the earliest palæolithic implements.

Mr. Reid Moir has carried out many excavations in the Suffolk Bone Bed, and after a very searching examination of a large number of artefacts from this deposit, concludes that these can be divided into five groups which show marked differences from each other These differences make themselves manifest in colour and condition, and in the types and flaking of the various specimens The characteristics mentioned serve to differentiate the groups, which moreover contain artefacts which exhibit reflaking. Such specimens, which are well known in later prehistoric cultures, represent those which were flaked by one man, and then patinated and stained, to be found afterwards and reflaked by another and later man. The later flaking shows usually a different colour from the earlier, and clearly cuts through the more ancient surface Further, the colour of the more recent flaking can be matched with that of another group, and so on, thus establishing the fact that below the Red Crag there exist five periods of human flaking upon the flints there assembled. Mr Reid Moir has carried out an exhaustive series of measurements of the specimens in each group and this supports the conclusions based upon colour and condition, as to the reality of the presence of the five groups mentioned.

The Suffolk Bone Bed is a typical residual deposit made up largely of the wreckage of strata at one

time existing in East Anglia, and broken up by the irruption of the sea into the area in Crag times At Bawdsey, on the Suffolk coast, the sea is to-day attacking a cliff composed of London clay, Red Crag, Glacial Gravel and surface material As these various beds are washed away, the heavier contents collect at low tide mark, and are forming a deposit similar in some respects to the Suffolk Bone Bed It is indeed highly probable that this was accumulated under analogous conditions, and it is possible that the mammalian remains of different ages in the Bone Bed, together with the flint implements, at one time occupied their respective geological horizons in the now vanished land of Suffolk

The mammalian bones and teeth in the Suffolk Bone Bed range from Upper Miocene to late Pliocene times, when this deposit was laid down It is possible that the earliest group of the sub-crag flint implements may date back to the earlier part of the Pliocene, or even to more ancient times, but this is not yet established The specimens of the earliest group, though exhibiting many archaic characteristics, cannot however be looked upon as the type of artefact likely to be made by the earliest representatives of the human race, but this group is obviously of an extreme antiquity, and its existence points to a much greater age for the human race than has hitherto been supposed It has long been recognised and accepted that man was present in East Anglia before the deposition of the Red Crag some 500,000 years ago, but it now appears that this period of time must be greatly extended to include the earliest group of the pre-Crag artefacts

The excavations which over a number of years have been conducted by Mr Reid Moir in the Suffolk Bone Bed, have been made possible by the invaluable financial help of the Royal Society, the Percy Sladen Memorial Fund and Mr T R Parkington of Ipswich

Artificial Production of the Hormone of the Corpus Luteum

THE transformations of cholesterol into the male sex hormone (androsterone) and of stigmasterol into a crude product having the biological activity of the corpus luteum hormone[1] have been rapidly followed by further important developments in this field of investigation of the sex hormones, and the corpus luteum hormone has now been prepared in a chemically pure state from stigmasterol and also from pregnandiol

The conversion of pregnandiol into the hormone was achieved by Butenandt and Schmidt[2] in a strikingly simple manner Having first shown that by partial hydrolysis of pregnandiol diacetate the nuclear acetoxy group was hydrolysed, they converted the monoacetate by a series of stages into the hormone, and showed thereby that the hormone was the $\Delta^{1,2}$ or $\Delta^{4,5}$ unsaturated diketone corresponding with pregnandiol These authors then found that pregnandiol could be transformed into the pure hormone by three simple stages, namely, oxidation to pregnandione, monobromination, and subsequent elimination of hydrogen bromide by heating with pyridine. As pregnandiol may be isolated from the urine of pregnancy without difficulty, there is no doubt that considerable supplies of the artificial hormone will be manufactured by this method

The isolation of the pure hormone from the degradation products of stigmasterol has been recorded by Fernholz[3] and by Butenandt and Westphal[4] As Fernholz and Chakravorty[5] have also shown that both cholesterol and stigmasterol may be degraded to the same 3-hydroxy-*nor-allo*cholanic acid, this conversion of stigmasterol into the corpus luteum hormone establishes the positions 3 and 20 for the two keto groups of the hormone The $\Delta^{4,5}$ position of the double bond is also regarded by Butenandt and Westphal as established by the formation of the hormone from stigmasterol, but since the position of the double bond of stigmasterol is based only on analogy with cholesterol[6] it is better to admit that the $\Delta^{1,2}$ position for the double bond of the hormone has not been rigorously excluded

Butenandt and Mamoli[7] have directed attention to the fact that pregnandiol is therefore a hydrogenation product of the hormone, and in the light of this conception it is easy to understand the presence of large quantities of pregnandiol in the urine during pregnancy, for the diol is thus seen to be the form in which the hormone is excreted, just as cholesterol is excreted in the form of its hydrogenation product, coprosterol.

The artificial hormone, like that prepared from corpus luteum extracts, exists in two polymorphous forms, one of which is readily converted into the other[8]

Temperatures of the Stars

IN a lecture before the Newcastle-on-Tyne Astronomical Society on December 12, Mr. W. M H. Greaves described the way in which stellar temperatures are derived from a study of the spectra of stars

All information regarding temperatures of the stars is derived from their light and its analysis. In heating a metal, while at first the radiation is almost entirely limited to the infra-red, with increase of temperature it includes wave-lengths in the visible part of the spectrum, and the proportion of blue to red light emitted increases as the temperature rises. But we cannot generally find temperature from colour, since the emissivity of bodies varies Nevertheless, our knowledge of the temperature of stars is derived from measures of the colour of star light, the source of which is the outer layers of the star

The 'black body', which theoretically absorbs all radiation falling on it and which, when heated, emits radiation of all kinds, is taken as a standard of reference. For such a body the proportions of emitted light at different wave-lengths are connected with temperature by Planck's formulæ Observation shows that, so far as measurement made between spectral lines is concerned, stars are emitting radiation in a

similar manner to black bodies, although they are actually 'grey body' radiators This being so, the continuous spectrum of a star can be matched in colour with black body radiation corresponding to some temperature, and this temperature is called the 'colour temperature' of the star

The light from a star consists of radiation from its surface and, to some extent, radiation from its lower layers which has only been partly absorbed on its way to the surface Theoretical investigation shows that, subject to certain hypotheses, the colour temperature of a star is about twenty five per cent greater than the actual temperature of the surface A comparison is made between the light emitted by the star and a laboratory source the colour temperature of which is known, and it is necessary to measure the ratios of the radiations from the star and the laboratory source at two separate wave lengths Applying Planck's formula for the ratio of the radiations from the latter at the two wave lengths, the measured ratios make it possible to derive the ratio of the radiations from the star at these wavelengths We then have the data to give the colour temperature

For measurement, the spectra from the star and laboratory source are photographed on the same plate and the photo chemical properties of the emulsion are utilised, since there is a relationship between the optical density or degree of blackening of the negative and the amount of light which caused it By an additional series of exposures of the plate to sources of light the relative intensities of which are known, spectral images are formed which enable a calibration curve to be made for any particular wavelength, and from this, differences in optical density can be converted into ratios of light The data obtained yield a quantity known as the 'colour function', which is related to colour temperature by a formula derived from Planck's formula, and thence the colour temperature of the star is obtained

Star light is reddened in passing through the earth's atmosphere and the observations have to be corrected for this effect Use is made of a system of stars the differences of colour function of which have been measured by a set of comparisons in pairs at equal altitudes above the horizon Pairs of stars chosen from this system are now photographed at unequal altitudes, and each such comparison yields a quantity, part of which is due to difference in colour function and part to the atmospheric effect As the difference of colour functions has been already obtained, atmospheric reddening can be determined and applied to comparisons between stars and the laboratory source used for comparison

Well-determined colour temperatures for a number of stars are now available as a result of the work at different observatories, and in the study of the relationship between temperature and other effects a striking correlation of temperature with spectral type has been found

Reorganisation of the University of Durham

THE University of Durham entered upon the second century of its existence three years ago with prospects somewhat clouded by controversies relating to medical education The Royal Commission appointed in March 1934 to report on the University's organisation and work found the constitution of the College of Medicine, which, together with Armstrong College, forms the Newcastle Division of the University, and also the University statutes, to be radically unsound in many respects and more particularly in their failure to confer on the University any control over the fate of one of its own professors

The recommendations of the Commission, embodied in the report just published (London H M Stationery Office, Cmd 4815 1*s* 6*d* net) provide for the reconstitution of the Newcastle Division as a single unit by the amalgamation of its two colleges under a head, to be appointed, in the first instance, by the Crown For the guidance of the organisation and development of medical education and the maintenance of close relations between the College and the associated hospitals, responsibility would be vested in a dean of medicine, to be *ex-officio* a member of the Court and Senate of the University and of the Council and Academic Board of the College and chairman of the Board of the Faculty of Medicine and of the Medical Studies Committee of the Academic Board

Of the two schools of thought with regard to the place and treatment of chemistry and biology regarded as part of the medical curriculum proper, the Commission has ranged itself emphatically on the side of the champions of the closest collaboration between the medical departments and the science departments in a university, the precise allocation of the teaching of the various frontier subjects being left to be determined in the light of the whole of the teaching power which is available, rather than by mere departmental considerations granted the desirability of relating the teaching of chemistry and biology to human physiology and anatomy and to medical problems generally, the one thing to avoid, in the interests of the teachers themselves as well as of the students, is a divorce of this specialised teaching from the university departments devoted to chemistry and biology

Medical education in Newcastle has been somewhat hampered for many years by inadequate premises Land for new buildings adjoining Armstrong College and opposite the Royal Victoria Infirmary has been acquired, however, and an extensive scheme involving the sale of the present site of the College of Medicine has for some time been under consideration Among the recommendations of the Royal Commission on the affairs of the University is one for the constitution of a temporary board of five persons, four appointed by the College of Medicine and one appointed by Armstrong College, to sell the existing premises and generally to arrange for the finance of the new building, to control the proceeds of sale and the greater part of the capital funds at present vested in the College, to assume control of the new site and supervise the erection of the new buildings and ultimately to transfer the premises together with any funds in its hands to the proposed new University College to be formed by amalgamation of Armstrong College with the College of Medicine A time limit not exceeding seven years would be fixed within which the Board would have to complete its activities.

The Durham Observatory, which was opened in 1841, is at present vested in the Council of the Durham Colleges, and is managed by a large body of curators, of whom some are teachers in Newcastle.

In the general debacle which overtook the teaching of science in the University of Durham in the eighteen-sixties, the study of astronomy survived and at times the astronomical work has been of considerable importance A seismograph was installed in 1929 Among the Royal Commission's recommendations for the future government of the University is a proposal that the Observatory should be transferred from the Council of the Durham Colleges to the University It is pointed out that, there being science departments in both the Durham and the Newcastle Divisions, the work of the Observatory should be regarded as a central university activity

University and Educational Intelligence

CAMBRIDGE —The General Board has issued a report on the future organisation of teaching and research in crystallography The following recommendations are made (1) The Crystallographic Laboratory shall be under the control of the Cavendish professor of experimental physics (2) All teaching of crystallography for Part I of the Natural Sciences Tripos shall be given in the Department of Mineralogy and Petrology All teaching of crystallography for Part II of the Natural Sciences Tripos shall be given in the Crystallographic Laboratory (3) The research facilities of the Crystallographic Laboratory shall be available for use by the staff of the Department of Mineralogy and Petrology and the research facilities of the Department of Mineralogy and Petrology shall be available in a similar manner for use by the staff of the Crystallographic Laboratory (4) There shall be an assistant director of research in crystallography who shall be responsible to the Cavendish professor for advanced teaching and direction of research in crystallography (5) There shall be an assistant in experimental research in crystallography whose duty shall be to help the assistant director of research He shall be appointed by the Cavendish professor, subject to confirmation by the General Board It is recommended further that Mr J D Bernal, of Emmanuel College, be appointed assistant director of research in crystallography from October 1, 1934, with a pensionable stipend of £500 a year

OXFORD —The contributions to science by the early members of Wadham College formed the subject of a public lecture in the Hall of the College on March 2 The speaker, Dr R T Gunther, stated that but for a most lamentable accident the lecture would have been delivered by the late Dr F. A Dixey, whose unrivalled knowledge of the connexion of the early fellows of the College with the foundation of the Royal Society had delighted many audiences in that hall Portraits of John Wilkins, Sprat, Seth Ward and Wren hang on its walls. Sydenham and Mayow were among its members Less well-known was the botanical work of Walter Stonehouse (1597–1655) and of Richard Warner (1713–75)

THE Royal University of Pisa is offering a research scholarship for the year 1935–36 under the Galileo Galilei Foundation The scholarship is open to all and, if a candidate is not Italian, he will be expected to carry out scientific research in an Italian institute during the tenure of the scholarship Further information can be obtained from the Rector of the University of Pisa.

THE first Regional British Isles Conference of the New Education Fellowship will be held at the University of St Andrews on August 13–22, under the presidency of Dr A D Lindsay, Master of Balliol College, Oxford The theme of the Conference will be "Education and Leisure How to Create a Democratic Culture" Two problems will be discussed, namely, education for leisure at schools and the provision of facilities and training for adolescents and adults so that they may be able to make use of their leisure after school life is over The subject of Dr Lindsay's address will be "Unemployment and Education" Further information can be obtained from the New Education Fellowship 29 Tavistock Square, London, W C 1

Science News a Century Ago

A Description of Upper California

At a meeting of the Royal Geographical Society on March 9, 1835, a communication was read from Dr Coulter describing Upper California, in which he had resided for two years The only portion of the country which was settled was mainly along the coast, the chief settlers being the Catholic missionaries, who sought to collect around their stations an Indian population, whom they taught, in a rude way, to till the ground and rear domestic cattle, while they compelled them to conform to their religious observances The great article of produce was black cattle In 1827 the missions possessed 210,000 branded cattle, and it was supposed not less than 300,000 unbranded The number of white inhabitants in Upper California was estimated by Dr Coulter at 6,000, and they were rapidly increasing, while the Indian population was decreasing The prospects for settlers in the north were good, the district being highly fertile, well wooded and watered The Tuli Lakes, although shallow in the dry season, furnished good facilities for the transport of wood, hides, etc Gold had been found in a stream falling into the Southern Tuli

Colliery Explosion near Wigan

According to the *Annual Register* for 1835, an explosion of firedamp in a coal mine near Wigan on March 9, 1835, caused the death of three women working in the mine There were only six persons working in the pit, which was a small one, but the pit was known always to contain a great quantity of inflammable gas Owing to this, a piece of cloth had been placed at the bottom of the pit to assist in ventilating it, but on the day of the accident this was not in place On a workman, Peter Tabernier, going into the colliery with a naked light, he noticed symptoms of an approaching explosion and hastened to get out of the pit, calling the others also to do so Unfortunately, before they could get out, the explosion took place, burning two men badly, and killing another man and three sisters aged respectively nineteen, seventeen and fourteen years "Had Tabernier," said the *Annual Register*, "taken the precaution of using Davy's safety lamp, instead of approaching with an unguarded light, which as soon as it approached, set fire to the explosive fluid, this accident in all probability would not have happened He had one of the lamps at home but out of repair, and through the extreme poverty to which he was reduced, he could not afford to get it repaired"

Egyptian Chronology

On March 12, 1835, Henry Hallam, the historian, wrote to Mrs Somerville directing her attention to an error she had made in her "Connexion of the Physical Sciences" On p 104 of this work Mrs Somerville had written "The Egyptians estimated the year at 365 d 6 h, by which they lost one year in every 14,601, their Sothiac period They determined the length of their year by the heliacal rising of Sirius, 2,782 years before the Christian era, which is the earliest epoch of Egyptian chronology" After pointing out that the Egyptian civil year was of 365 days only and the Sothiac period was 1461 years, not 14,601, Hallam said "I do not see how the heliacal rising of Sirius in any one year could help them to determine its length By comparing two successive years they could of course have got at a sidereal year, but this is what they did not do, hence the irregularity which produced the canicular cycle The commencement of that cycle is placed by ancient chronologers in 1322 A C It seems not correct to call 2782 A C 'the earliest epoch of Egyptian chronology', for we have none of their chronology nearly so old, and in fact no chronology, properly so called, has yet been made out by our Egyptian researches Certainly, 2782 A C is a more remote era than we are hitherto warranted to assume for any astronomical observation"

A History of British Fishes

Among its short notices of new books, the *Athenaeum* for March 14, 1835, referred to "A History of British Fishes" by William Yarrell "Here is the first number," it said, "of a beautiful work, to be completed in fourteen monthly parts, illustrated by woodcuts of all the species, and numerous vignettes The name of Mr Yarrell is sufficient guarantee for the accuracy of the work, and we can assure our readers that the exquisite beauty of the illustrations leaves nothing to be desired It promises, when complete, to be a worthy companion to Bewick's 'Birds'—and we know not that we could say more in its praise" Yarrell, who was born in 1784 and died in 1856, was a successful business man and head of a newspaper agency Devoted alike to sport and natural history, he belonged to the Linnean, Zoological and Entomological Societies His collections of fishes and birds were purchased for the British Museum

Chemistry at Oxford

In the Lent Term, 1835, Dr Daubeny began a course of chemical lectures in the basement of the Old Ashmolean Building at Oxford to an audience, some of whom rose to great distinction Among them were Archibald Campbell Tait, F R S, then a newly elected fellow of Balliol, who afterwards became headmaster of Rugby, 1842–60, Bishop of London, 1856–68 and Archbishop of Canterbury, 1868–82; William Dudley Ryder, afterwards arbitrator in the Mixed Court of New York; Reginald Windsor West, seventh Earl Delawarr; and John Bennett Lawes, who had matriculated at Brasenose College in 1833, and who founded the Rothamsted Agricultural Experiment Station ten years later. In those days, it was quite usual for persons intending to take holy orders to attend scientific lectures.

Societies and Academies

LONDON

Royal Society, February 28 J MELLANBY The supposed coagulation of oxalate plasma by trypsin The action is due to the conversion of prothrombase to thrombase by the ionised calcium contained in the trypsin solution The quantity of calcium required to coagulate oxalate plasma is determined by the thrombokinase content of the plasma Plasma containing $N/80$ potassium oxalate and an optimal quantity of kinase may be coagulated by the addition of $N/800$ calcium chloride This fact indicates the avidity of kinase for securing the calcium ions to the prothrombase kinase system Mammalian blood collected directly into a solution of potassium oxalate obtains kinase relatively slowly from the cells of the blood The interval of time after leaving the blood vessels is greater than that required for the precipitation of 75 per cent of the total calcium of the blood by the potassium oxalate G SALT Experimental studies in insect parasitism (3) Host selection Parasites attack only certain hosts, but why they choose some particular species and reject others is unknown Two strains of the parasitoid *Trichogramma evanescens*, reared exclusively on *Sitotroga* and *Ephestia* respectively for 63 and 43 generations, developed no dependence on, or preference for, their respective hosts Both strains preferred *Ephestia*, but the preference was not a specific one for *Ephestia* but a preference for *Ephestia* as the larger host Ovipositing females of *Trichogramma* attacked a number of true hosts from which their progeny successfully emerged, several unsuitable hosts in which their progeny were unable to develop, and a variety of false hosts in which they were unable even to lay their eggs The principal criterion used by ovipositing females of *Trichogramma* in the selection of their hosts is that of size G FRAENKEL A hormone causing pupation in the blow-fly, *Calliphora erythrocephala* This secretion is produced 16 hours before pupation (at 20° C) The hormone producing organ is either the ganglion or in its immediate neighbourhood After the hormone has been discharged, pupation can be successfully accomplished without the co-operation of the ganglion The atmospheric oxygen required for the darkening of the pupa is brought to the skin through the tracheal system.

PARIS

Academy of Sciences, January 21 (*C R.*, 200, 269–356) The president announced the death of Emanuele Paterno di Sessa, foreign associate. Cinematograph Films and the Home Office

RECENT correspondence in the *Manchester Guardian* has directed public attention to a grave risk threatening that general use of cinematograph films in education and research, which has made such rapid and desirable progress in recent years For it is admitted that the Home Office proposes to bring the smaller sorts of cinematograph projectors, and the films on cellulose acetate base which are commonly supplied for use with them, within the scope of new regulations purporting to be made under authority of the Cinematograph Act 1909 in the interest—so it is alleged—of greater safety for the public

Now the Cinematograph Act is concerned solely with the use of apparatus "for the purposes of which inflammable films are used" it gives no authority whatever "for securing safety" in the use of any film which is not inflammable When the Act was passed, in November 1909, scarcely any projectors were in use except those for films of 'standard' 35 mm. width, and scarcely any films were published except on 'cellulose nitrate' base, which is highly inflammable, igniting at about 230° C, and burning with almost explosive violence. It was clearly in the public interest that the use of such a substance in public assemblies and in necessary proximity to an arc-lamp should be strictly regulated

In 1909, however, this defect of the earlier films was already leading to the provision of a substitute, the 'cellulose acetate' base, which does not inflame at all below a red heat, melts before it ignites, smoulders rather than burns, and often extinguishes itself The Cinematograph Act accordingly dealt only with projectors using 'inflammable' films But the 'non-flam' base has even now one serious disadvantage, that it is liable to warp in use, and consequently is not suitable for films so wide as the 'standard' 35 mm gauge

For all 'sub-standard' widths down to 9 mm, and consequently for cheap and portable projectors, adequate for school classes and other small audiences, as well as for laboratory work and private entertainment, the 'non-flam' film has revolutionised cinematography, as the Kodak camera with its roll-holder of film negatives revolutionised photography forty years ago Schools of all grades, laboratories and museums, clubs and churches, have been equipped with

sub-standard projectors, thousands of film exhibitions are given annually with the same freedom as lantern lectures, and many lantern slides, too, are now made on 'non-flam' base, which is both lighter and less fragile than glass For Kodak negatives the 'non-flam' film has practically driven out the earlier bases, some of which were dangerously inflammable No accident from a public exhibition of 'non-flam' film has ever been reported · a solitary mishap at Dulwich College was shown to have resulted from the inadvertent issue of an inflammable film from a Government department The Post Office has now its own film factory and issues 'non-flam' films for public use. The Board of Education allows large sums to be spent to install 'sub-standard' projectors for open use in schools

The Cinematograph Act, however, did not define an 'inflammable' film, and the Home Office, after leaving sub-standard projectors, with their 'acetate'-base films, unmolested for nearly twenty-five years, has now admitted, under question, that it is intended to "adapt the regulations to present conditions" and that "one of the points to be dealt with is the relaxation, in favour of slow-burning films, of certain requirements necessary for fast-burning films". The implication here is that all films are "inflammable" within the terms of the Cinematograph Act, and that unless and until the Home Office "relaxes" its regulations, any film exhibition is liable to be regarded as a breach of the Act, unless it takes place under the very stringent regulations proper for 'standard' size films on 'nitrate' base

It is difficult at first sight to believe that there is anyone who wishes to restrict the free use of sub-standard projectors or the general employment of films in private, in education and research, or in places of entertainment other than those larger halls where 'standard' projectors, and (consequently) inflammable films are still indispensable But the premature glee with which certain newspapers have proclaimed the end of the 'non-flam myth' seems to betray such a desire; and it is obvious that if people can see the kinds of films they desire, co-operatively, safely and at small cost, without 'going to the pictures', it is not very good for interests which at one time had almost a monopoly of the cinema, as professional photographers monopolised photographs and lantern-slides before the days of the Kodak.

It is especially unfortunate, also, that this outcry about 'non-flam' films should have been confused in some minds with the quite different question whether private, social and educational exhibitions should be 'censored' or otherwise controlled in the supposed interests of morality, political orthodoxy, or what are popularly described as 'box-office' considerations. For, whereas 'non-flam' films and sub-standard projectors have until now been free from official interference on the ground of public safety, most authorities responsible for licensing halls for the exhibition of 'standard' and therefore 'inflammable' films, though legally concerned only with the personal safety of audiences, have in fact agreed to permit in their areas only films 'approved' by the British Board of Film Censors, a body which was set up by the film trade itself, shortly after the Cinematograph Act was passed

This confusion of public safety with public morality has been the weakest point in British film administration throughout. If the public needs protection against improper or subversive films, it would seem reasonable that this should be assured under the laws regulating improper or subversive behaviour in general If a censorship should be deemed unavoidable, let us have an official censor, responsible to one of the Secretaries of State, not to the 'trade', which has an interest in the matter, and not always a British interest.

Further, if "for securing safety" the Home Office wishes to "adapt the regulations to present conditions", it can make sub-standard projectors as safe and foolproof as their recognised public utility demands, simply by making it an offence, under the Cinematograph Act or otherwise, to manufacture or offer for sale films on 'nitrate'-base of any width less than the standard 35 mm size Any restriction or discouragement of the present general use of the sub-standard projector would be a disaster in public education, and also in the many branches of scientific research and teaching in which this valuable piece of apparatus is employed

The National Institute of Sciences of India

FURTHER details of the Indian Institute of Sciences, to which brief reference was made in NATURE of January 12 (p. 59), are now available. **Elsewhere in this issue (p. 441) we print an article summarising the circumstances of its inception and recording the proceedings of the inaugural meeting. The desirability of having in India a national academy has long**

been felt, and this found expression a year ago in the appointment by the Indian Science Congress of a strong committee to elaborate a scheme for the establishment of an All-India Academy It was feared by many that the work of this committee might have been jeopardised by the registration last June of an 'Indian Academy of Science' by Sir C V Raman in Bangalore There were thus three bodies of 'academy' standing in India, the premier society—the Asiatic Society of Bengal—the United Provinces Academy of Science, and the new Indian Academy of Science Fortunately, the common sense which has always been such a marked feature in the organisation of the Indian Science Congress, has enabled its committee to surmount all apparent difficulties and to secure the adherence of the officials of these three societies to the new Institute

The Institute, with its headquarters in Calcutta, has received the support of all the most prominent men of science in India, it has started with one hundred foundation fellows, and in the future not more than ten will be elected annually. The fellowship will obviously, therefore, be a much prized distinction and since it is intended later to apply for a Royal Charter, the Institute will in effect become a Royal Society of India It is not proposed that the Institute should publish a journal, publication will remain as one of the functions of the co-operating academies, which it is anticipated will be increased by the formation of academies in Bombay and in the Punjab It will, however, issue a Proceedings summarising the papers read before these societies, and it will be prepared to assist them in the publication of expensive memoirs An annual report, reviewing the progress of science in India, will also be issued, thus reviving on a broader basis that prepared formerly by the now defunct Board of Scientific Advice The Institute proposes also to organise symposia on subjects of general and scientific interest A further activity, on which emphasis is laid in the presidential address, will be "to promote and maintain a liaison between men of science and men of letters" Whilst a National Institute of Arts and Letters has still to be formed, the desired liaison has been effected in an indirect manner by the fact that one of the co-operating academies, the Asiatic Society of Bengal, is both an academy of science and of letters

Of far greater importance, however, in our opinion, are two other functions referred to by Dr Fermor (*a*) to appoint committees to which the Government and other bodies can apply for advice, and (*b*) to secure and manage funds and endowments for scientific research We advocated recently (NATURE, 134, 789, 1934) the formation in India of a National Research Council, and these two functions, if fully exploited, will in effect make the Institute such a Council We understand that the Government of India has allocated a grant of 12,000 rupees (£900) per annum to the Institute, and we do not doubt that further funds, from both public and private resources, will be placed at its disposal

The formation of the National Institute is the most important development in the organisation of scientific activities in India which has occurred since the foundation in 1913 of the Indian Science Congress It is but fitting that the Institute should owe its inception to this body

Reviews

Embryology—Biological, Philosophical and Theological

A History of Embryology By Dr Joseph Needham. Pp xviii + 274 + 16 plates. (Cambridge At the University Press, 1934) 15*s* net

LOVERS of Tristram Shandy will remember that passage in which Sterne gives a cut of his ironic whip at the learned Catholic doctors of the Sorbonne, who in their zeal to save souls had given a very precise account of the principles governing the baptism of unborn children, not forgetting detailed practical instructions for achieving it "avec une petite canule sans faire aucun tort à la mère". The Anglican divine suggested a more embracing method, "of baptizing all the *homunculi* slap-dash" beforehand, which he assures his readers could be done "avec une petite canule sans faire aucun tort au père"

We have here a very good example of the interweaving of theological and biological embryology. The *homunculi* are of course the spermatozoa, in the head of which, certain early microscopists had averred, miniature men had their habitation, ready to expand their preformed anatomy in the nutritive soil provided by the female Some had insisted that they had actually observed the manikins, others had achieved the almost greater feat of asserting their existence on grounds of logical necessity. (Was it not the great Bonnet,

writing on the allied subject of preformation, who claimed the fantastic doctrine of *emboîtement*, according to which our first parents contained all future generations, after the fashion of Chinese boxes in an infinite regress, as "one of the greatest triumphs of rational over sensual conviction".)

In any case, it was the biological discoveries of the seventeenth microscopists, quite apart from their metabiological speculations, which enabled the eighteenth century Sterne to reduce *ad absurdum* the arguments of the theologians, based as they were upon the facts and ideas of an earlier age

Embryology is full of such interactions How could it be otherwise when the recurrent miracle of generation is concerned ? Let us remember that it was not until the middle of the eighteenth century that the early stages of development, demanding the microscope for their elucidation, were in any animal adequately described, and not until the middle of the nineteenth that fertilisation was observed, the concept of the continuing stream of life established, and proof given of the essentially equal contributions made by father and mother to the offspring. Yet offspring were all the time being produced With their production, the gravest questions were bound up—scientific, philosophical and theological. It was imperative to give some answer to these questions, for not only will the speculative itch not be denied, but also far-reaching theories of existence and practical problems of personal salvation hinged upon them. In the absence of any real basis of fact or any framework of established scientific principle, speculation both could, and did, run riot.

Dr. Needham's book, which covers the history of embryology up to the beginning of the nineteenth century, is essentially a history of the invasion of this speculative orgy by hard-won fact and dawning experiment The invasion has been slow, and now and again, as in the Dark Ages, was hurled far back. But on balance it progresses, until by the early eighteenth century it has established a permanent footing and prepared the way for the increased momentum of its subsequent advance.

Embryological knowledge and speculation are conditioned by their environment. In certain cases, factual advance is shown to depend upon technical achievement. The most obvious example of this was, of course, the advance consequent upon the invention of the microscope. Dr. Needham points out, however, that it took longer than might have been expected for embryology to take advantage of the new tool ready to its hand. Harvey, for example, seems never to have utilised anything but hand lenses Or the temper of the time may prevent the speculative men of science from utilising the resources available to them. The general contempt in which manual labour and the mechanic arts were held in classical Greece diverted into mere speculation much energy that might have led to real advance In such periods as the Middle Ages, when the dominance of theological principles prevents the appeal to fact and experiment, and those like the eighteenth century when pure reason is enthroned above the pedestrian senses, men take to the wings of speculation, and distort their thinking with deduction from preconceived principle We have cited the example of Bonnet Another is the belief that the shape of the egg will enable one to prophesy the sex of the chick This is based on the two principles that the circle is the perfect form, and that the male sex is more perfect than the female from which it inescapably follows that cockerels will hatch from the less pointed eggs

This overflowing of scientific speculation into abstract principle may have important practical consequences. Aristotle, as is well known, advanced the theory that the mother merely provided the soil in which the seed of the male might grow and develop Dr Needham points out the bearing of this view on the growth of the patriarchal system of social organisation, and on the widespread practice of killing captured males but keeping the women as slaves and concubines Or again, we may refer to the speculations concerning the entry of the soul into the embryo With the rise of Christianity, these became of practical importance Since according to canon law the embryo has a soul from the fortieth day onwards, the embryo that dies unborn is condemned to damnation if it be not baptised ; and this led to occasional barbarities in cases of obstruction of birth. More important, it led to the view that abortion was murder, a view duly reflected in a change in practice and in law. Both the Greeks and the Romans had taken a lenient view of abortion, or like Plato and Lysis had actually defended it ; but from the fourth century A.D. onwards it became both a sin and a crime. It will be of great interest to see what effect modern discoveries concerning the nature of fertilisation and the facts of early development will have on the theological and moral attitude to the problem. Already in the eighteenth century we saw Sterne pushing logic to its conclusion with his proposal for spermatozoan baptism ; and now that, with the progress of endocrine research, we are likely to wake up any morning to the discovery of a physiological method of preventing implantation, or of dislodging the early embryo from the uterine mucosa before it has established its

vascular nutritive system, we may speculate whether some subtle distinction may not be drawn between an embryo and a mere blastocyst, between criminal abortion and permissible denidation There is much virtue in terminology

Dr Needham is fully alive to the implications of the Marxian view as to the conditioning of scientific advance by economic conditions, and makes some valuable comments on the bearing of the social and economic status of the medical man and the midwife upon the advance of embryology One of his most interesting sections is devoted to a discussion of the various 'limiting factors' affecting steady scientific advance Among these he distinguishes the relation of the scientific worker to his environment, both the economic environment and the environment of idea, the degree of co-operation among investigators and scholars, including the provision of facilities for publication, material technique, such as fixing reagents, the microscope and the microtome, mental technique in the shape of convenient terminology, fruitful concepts and general attitude; and finally the proper balance between speculation, observation and experiment As he says, "We may thus regard the progress of knowledge . as governed by a reaction-chain, one link of which may at any given time be slower than all the others, and hence may set the speed for the whole"

Of course, Dr Needham's book is not mainly concerned with such general ideas They emerge in relation to the historical facts These are set forth in detail, in many cases with a new emphasis, and often with the inclusion of new or little-known material But, although they constitute the backbone of the book, within the limits of a review we cannot touch on them

To tell such a story adequately needs biological and historical knowledge, familiarity with the basic problems confronting embryology to-day as well as a sympathetic insight into those that confronted it at different periods in the past, industry, miscellaneous learning, and a philosophic spirit Dr Needham is one of the few biologists to possess these varied qualifications, and the result is a valuable contribution to the subject.

Naturally, there are a few points for criticism. Many who are impressed by the plasticity of the regulatory phase of development and by the modifiability of the embryo through environment will quarrel with the description of modern embryology as 'predetermined epigenesis'. To the author's citations on p. 292 concerning the dangers of too firmly-held speculation, he might have added the obstinate resistance of the phylogenetic embryologists in general and the full-blooded believers in recapitulation theory in particular to the advance of *Entwicklungsmechanik* He is scarcely fair (pp 40–41) to the very real and deep difference between the true teleology which appeals to final causes and the pseudo-teleology which is the necessary outcome of accepting natural selection as a *vera causa* in evolution

At the close of his volume Dr Needham appears unduly gloomy "Experimental embryology," he writes, "Morphological embryology, Physiological embryology, and Chemical embryology form to-day a vast range of factual knowledge, without one single unifying hypothesis . . " Here we cannot follow him On the morphological side, the broad ideas of comparative phylogeny still hold, the principle of recapitulation, however shorn of its formal absolutism, still yields indispensable service On the chemical side, Dr Needham himself has demonstrated the adaptational and phylogenetic meaning of certain large bodies of fact, for example the biological meaning of the numerous facts centring round the cleidoic egg Elaborate developmental processes like amphibian metamorphosis are proving amenable to a physiological explanation It is being shown that mutation is affected by differentiation, the expression of genes, such as that of Himalayan coat colour in rabbits, has been explained in terms of position and physiology, and the concept of rate of action, both for the effects of individual genes, for the co-ordination of complex processes of differentiation and for growth, is proving exceedingly fruitful in the hands of Goldschmidt, Ford, Witschi and others In experimental embryology, the distinction between the plastic and the determinate phase and the realisation that the time of onset of the latter can be shifted, has broken down the old distinction between 'regulation' and 'mosaic' eggs, and established a comprehensive unity The mathematical formulation of growth, both absolute and relative, is becoming serviceable The earlier speculations of Child are being reshaped by Weiss and Waddington into a serviceable field theory The work on organisers (to which again our author has made his distinctive contribution) is linking up certain important facts of embryology with the general theory of hormones

Many of the principles that are emerging are still themselves, it is true, somewhat embryonic but they exist, and will develop We cannot expect, in such a complex subject as embryology, to find a single all-comprehensive unifying principle, any more than we expect it in physiology or biochemistry Dr Needham has promised us a sequel to the present volume, to cover the nineteenth century and modern periods of embryology. It will be eagerly awaited · but it is to be hoped that he will recover his theoretical optimism before undertaking it.

Science and Citizenship

The Frustration of Science By Sir Daniel Hall, J G Crowther, J. D Bernal, Prof V. H Mottram, Dr. Enid Charles, Dr P A Gorer, Prof P M S Blackett Foreword by Dr Frederick Soddy Pp 144 (London George Allen and Unwin, Ltd , 1935) 3*s* 6*d* net

AMONG the more hopeful signs in the last two years is the growing sense of social responsibility among individual men of science, and the widespread impatience with sabotage of foodstuffs or other products in a world in which hundreds of thousands are still insufficiently nourished or clothed Naturally enough, both scientific workers awakened to a sense of social responsibility, and the ordinary citizen indignant at so much poverty and distress in the face of the incredible abundance with which science has endowed mankind, have been more concerned to find ways and means of appropriate action than to pause to establish the fundamental causes of this startling but distressing paradox If, however, we are to make constructive suggestions and evolve a wise policy rather than adopt temporary expedients or palliatives, it is essential that diligent inquiry should be made into the underlying causes of what has rightly been termed the frustration of science

The bitter charge that science has enthroned the wastrel holds too much painful truth to be ignored Common prudence warns us of the dangers of continuing to place more and more power in the hands of those intellectually and morally incapable of using it wisely Even if men of science as a whole have been much too prone to adopt an attitude of indifference to social questions or even to regard original thought on these matters as socially dangerous and professionally reprehensible, not even the most cynical could charge the scientific worker with the deliberate prostitution of his discoveries and inventions to the infliction of suffering, the multiplication of unemployment, or of the risks and horrors of war.

The essays which appear in this volume, following a foreword by Prof F Soddy, demonstrate most effectively how impossible it is for the scientific worker to remain indifferent either to the social and economic consequences of his work, or to those forces which determine even the direction which his work shall take

Inevitably some provocative matter is to be found in a book of this type, but its arguments are the more impressive because no claim is advanced for exceptional powers for scientific workers as a class, as compared, for example, with politicians. On the contrary, the tendency to place all the blame on the politician is vigorously attacked The book pleads not so much for the participation of the scientific worker in the actual task of government on such lines as those outlined by Prof Miles Walker in a well-known address, or even of the contribution of a detached, scientific attitude to political questions, as for the body of scientific workers to throw in their lot with one or other of the main contending forces

This contention will no doubt disappoint many who believe that the study of difficult political, social and economic questions by the scientific method is a most fruitful line of advance Such scientific workers will, however, find a good deal of food for thought in the frank disclosure of forces which at present prevent any such attitude of mind or attack on these questions The problem as visualised by this book is that of securing the conditions in which a scientific approach to these questions becomes possible

The facts marshalled in support of this thesis sometimes make bitter reading What a bankruptcy of mind and leadership, for example, is betrayed in proposals to restrict output in face of over-production when more land, more labour, more skill are still required to supply the greater part of the population with the mixed dietary of a better-class family in place of a diet almost exclusively existing of cereals. The application of science to the distribution of the productive capacity of the world and to the government of its peoples demands a wealth of directive skill and a technique of national organisation which necessitate in effect a social revolution as well as a complete change of outlook

Aviation tells the same story. Contrary to popular belief, technical development in war-time is slower than in peace-time, although the British expenditure was four times as great in 1914–18 Long-distance aviation has been severely frustrated by the refusal of Governments to allow air routes to be operated in the most economical and effective manner over their territories. "First over Everest" contains painful evidence of the hindrances in the way of science placed by nationalistic Governments and military needs, and J G Crowther asserts that aviation will remain frustrated as long as it is not conducted primarily to serve the creative classes

Even the chapter on science and industry discourages any easy optimism that all is well here also. The waste of expenditure on war research, the inefficiency of scientific work in the universities, the general lack of direction of research even in physical science, and the loss of freedom on the part of the scientific worker, are all matters on which Mr. J. D. Bernal causes us furiously to think. Again, there is the still considerable time-gap between theoretical discoveries and their

application, the immense amount of technical knowledge still unappropriated by society or industry even for the relief of suffering, the way in which the economic structure itself opposes technical change and the adoption of new methods or standards of living, limiting alike expenditure on research and utilisation of existing knowledge.

This sombre picture of the way in which scientific development may be held up by lack of support or turned to trivial or destructive uses cannot be ignored by the man of science He at all events should see through the fallacy of a demand for less science and a return to simpler times, when what is really needed is the application of science to the convenience of living instead of to profit-making Nor can he fail to be alive to the danger of the degeneration of science under what is called economic nationalism, and the narrowing of its functions, or the way in which professional efficiency and a scientific outlook in the practitioner are threatened by the conditions under which he is called upon to practice, as in the medical profession to-day

The exact relations between scientific workers and political organisations may be open to debate There can be no question, however, as to the need for much more open-mindedness on the part of all men of science towards the social and industrial problems of their environment to-day Even from the point of view of the advance of science itself they must face those problems Much more must they accept the challenge, corporately and individually, if they care anything for the enrichment of mankind with the vast resources of material well-being and leisure which science has now put within our power That era of plenty can only be achieved as men of science face frankly such problems as are presented in this book and, faithfully proclaiming the truth, strive as earnestly and disinterestedly for their solution, for the distribution of wealth and the science and art of living as in the past they have striven for the acquisition of the knowledge which places an age of plenty and of leisure within the reach of all

Development of High-Speed Aircraft

Air Ministry Aeronautical Research Committee Reports and Memoranda No 1575 *Collected Reports on British High Speed Aircraft for the 1931 Schneider Trophy Contest* Pp iii+100+60 plates (London: H M Stationery Office, 1934) 10*s*. net.

THIS monograph describes the development of the British aircraft for the Schneider Trophy contest of 1931, the preparations for and the actual contest, also the successful attempts on the speed record afterwards It is mainly concerned with the technical aspects, although a tribute is paid to the great skill of the pilots, without which the successes could not have been achieved

The book is divided into sections, each written by the persons mainly responsible for the work described, and although it forms a connected whole, the individual reports are self-complete

Section 1 is an introduction by H M Garner, giving a brief description of the history of the 1931 contest and a summary of the contents of the monograph In Section 2 the development of the design and construction of the *S 6A* and *S 6B* are described by R J Mitchell, the chief designer of Supermarine Aviation Co (Vickers), Ltd Although the design was based on the *S* 6, the Schneider Trophy winner of 1929, there were a number of problems which required further solution, and these were dealt with by Mr Mitchell in co-operation with the Air Ministry and National Physical Laboratory staffs Probably the most difficult problem was the provision of adequate water- and oil-cooling

Section 3 describes the development of the engine by Messrs Rolls-Royce, Ltd Although the external shape of the 1929 engine was scarcely altered, almost the whole of the working parts of the engine had to be re-designed The airscrews were all of the Fairey-Reed type, and a description of the development of them is given in Section 4

Section 5, describing the wind tunnel tests, is written by the National Physical Laboratory staff The tests were made on as large models as possible in the Duplex wind tunnel at the National Physical Laboratory in order to reduce the scale effect For the first time in the history of these contests a large amount of full-scale data was collected This is described in Sections 6 and 7 and also in a separate report (R and M 1472)

The flying experiences of the high-speed flight are summarised in Section 8, and the medical aspect of high-speed flying is discussed in Section 9.

The monograph concludes with Section 10, giving a short descriptive account of the Schneider Trophy contest and the two speed record flights It is evident that the speed in the contest could have been improved had not instructions been given to take no risks on the turns and to keep the water temperature of the engine at a safe level by throttling A subsequent speed record flight of $407\frac{1}{2}$ m p h was made

The monograph illustrates the many aspects of aeronautical research which have to be considered in the development of racing aircraft. It should certainly be read by all aircraft designers, and in a broader sense it is an excellent example of how scientific and technical experimentation upon a specific question should be organised.

Short Notices

The Generic Names of the Holarctic Butterflies By Francis Hemming Vol 1 *1758–1863* Pp viii + 184 (London British Museum (Natural History), 1934) n p

THIS book aims at providing a list of generic names proposed for the holarctic butterflies between the years 1758 and 1863, inclusive It also attempts to give the correct fixation in so far as typical species, or genotypes, are concerned Mr Hemming has based his results and conclusions on an exhaustive first-hand examination of the whole of the literature concerned. Entomological workers have long been hampered by doubts obtaining relative to the correct names of so many of the insects they study Among these uncertainties, generic names are paramount, while specific names are of lesser importance and would prove of little difficulty once uniformity of generic nomenclature could be attained

With few exceptions, the strict application of the present International Code of Nomenclature has been followed, in certain instances widely used names, especially those of insects of economic importance—the strict application of such rules would result in unnecessary confusion It is, therefore, suggested that with regard to seven well-known genera, the application of the rules be suspended and that such names be placed in the list of *nomina conservanda.* In the appendix at the end, the relevant articles of the nomenclature code that have been followed are given and are thus available for ready reference It is to be hoped that the International Commission of Zoological Nomenclature will, as soon as may be possible, exercise its plenary powers and decide in favour of the recommendations put forward Mr Hemming has evidently carried out his task with great care, and the result of his labours will be welcomed by lepidopterists of both Europe and North America

Ancient Egyptian Materials and Industries By A. Lucas Second edition, revised. Pp xii + 447. (London · Edward Arnold and Co, 1934) 16s net

IN this volume the author has published with a change of title a second edition of his "Ancient Egyptian Materials" (1926) Those who are acquainted with the book in its earlier form will scarcely need assurance of the merits of the revised edition The author has incorporated much fresh material, which has accrued from his further researches Three chapters have been added as the result of much expansion and rearrangement; and the ancient industries, which received little more than mention, have now been treated in some detail. Among the industries with which Mr Lucas deals are faience- and glass-making, metal-working, pottery-making and stone-working, while among the new materials added are coral, cosmetics, perfumes and mother-of-pearl. Many additions have been made to the references from the Greek and Latin writers, and the chemical analyses, now much expanded, again appear as an appendix.

Electrolytes By Prof Hans Falkenhagen Translated by R. P Bell (International Series of Monographs on Physics) Pp xvi + 348 (Oxford: Clarendon Press, London Oxford University Press, 1934) 25s net.

DESPITE the existence of some excellent English works on the subject, this translation of Prof Falkenhagen's treatise is a very opportune addition to physical literature The book is thoroughly physical in its outlook, and the mathematics employed serves to clarify and to emphasise the physical concepts

A notice of the work would become a mere catalogue if it attempted to give the reader an adequate notion of the topics dealt with; suffice it to say that the book begins with Faraday, and, after discussing ideal dilute solutions and weak electrolytes, proceeds by way of Lewis's theory of activities to a study of those theories involving interionic actions which have, during recent years, dominated the subject

It is sufficient commentary on the rapidity with which the subject is developing to note that this volume—a translation of the German edition of 1932—has been brought up to date by the addition of sections dealing with recent extensions of Bjerrum's theory, with Onsager's treatment of the dissociation field effect, and with applications of quantum mechanics to electrode processes

Scholarly and very fully-documented, the book is indispensable to any serious student of electrolytic phenomena A F

Palestine and Israel Historical Notes By Sir Flinders Petrie Pp 99 + 16 plates (London Society for Promoting Christian Knowledge, 1934) 3s 6d net

SIR FLINDERS PETRIE here describes in popular form the contacts between archæology and scriptural narrative of early Israelitish history, mainly in the results of the excavations of the British School of Archæology in Egypt in Southern Palestine The cardinal point of his argument, however, is the consistent character of the patriarchal narrative, when the years of the Biblical account have been subjected to amendment on lines for which there is strong grounds of probability The later dating of the Exodus is then shown to fall into place

The treatment of the Biblical text throughout is essentially conservative The author holds that the results of textual criticism are largely irrelevant. The narrative is not a jumble of sources little better than fortuitous, but, he maintains, can be shown to be a carefully considered selection from a variety of sources in the construction of a complicated, but consistent, story

---

WE regret that in referring to "The Kinetic Theory of Gases", by Prof Leonard B Loeb, in NATURE of March 9 (p 390), the publisher's name was incorrectly given as Messrs. Chapman and Hall, Ltd. The book is published by The McGraw-Hill Publishing Co, Ltd, Aldwych House, Aldwych, London, W C.2.

The Uses of Rubber

By G. E COOMBS

THE rubber industry of to-day is concerned almost exclusively with the exudation which results from wounding certain of the tissues of *Hevea brasiliensis*, a large tree 80–100 ft tall which is indigenous to the Amazon basin The tree will grow almost anywhere in the belt 10° north and south of the equator, though it does not compete economically at elevations above 2,000 ft Its translation from the Amazonian forests to plantations in the tropical Middle East is a romantic story associated with the names of Markham and Wickham

The development of these plantations has been very rapid, the area having increased by fifteen times in the past twenty years, until to-day the production side of the industry is concerned with 7–8 million acres of plantations, chiefly in British Malaya, Netherlands Indies, Ceylon and French Indo-China, capable of producing more than a million tons of the product annually This enormous aggregate area carries the progenies of the seeds collected by Wickham (1876) from the Amazon basin

The exudation referred to above is known as hevea-latex, since *Hevea brasiliensis* is only one of some four hundred plant species which elaborate juices containing rubber or rubber-like substances It is generally ivory white in colour, and tends towards the consistency of cream It has practically the same density as water, and an average sample contains 35 per cent of rubber as a colloidal suspension of tiny globules which are negatively charged. Rubber itself is an unsaturated hydrocarbon with an empirical formula $(C_5H_8)_n$, where n possibly approximates to 1000 The suspension is very unstable, and if left to itself it develops acidity, when its globules coalesce to produce a coherent junket-like coagulum Once the latex is coagulated it is not possible to reverse the process and recreate the suspension The coagulation can be speeded up and be made complete by, for example, the addition of dilute acetic acid It can also be prevented by the addition of ammonia, whereby the latex is kept 'sweet' and stable. In such condition it can be concentrated by creaming or centrifuging; further, with the addition of protective colloids, for example, soaps, glue, casein, etc., it can be concentrated by evaporation

Very little is known of the biochemical processes which lead to the formation of latex in the tree, or of the rôle it plays in its life-processes. It occurs, and is probably elaborated, in a definite system of branching tubes, associated with the vascular tissue of the tree, which finds its highest development and greatest density in the inner bark of the base of the trunk, whence it is procured by 'tapping' Speaking generally, the raw rubber of commerce is merely the dried coagulum of hevea-latex, and except for the preparation of preserved latex, an operation confined as yet to a few estates, the producing side of the industry finishes with the shipment of the dried product This product is of limited utility Among other things it becomes tacky with heat, stiffens with cold, and perishes with age Early attempts to use it entailed its reconversion to liquid form by the use of solvents (Peal 1791 and Mackintosh 1819)

The rubber manufacturing industry of to-day was made possible by two empirical discoveries Hancock (1820), seeking to shred the material on spiked rollers, discovered that the operation produced a plastic mass which could be moulded to shape This process of mastication remains to-day as the preliminary in practically all manufacturing operations We now know that oxidation and the generation of heat are the factors responsible When, however, Goodyear (1839) and Hancock (1842) discovered independently that raw rubber subjected to heat in the presence of sulphur produced a much toughened product, relatively insensitive to temperature changes, and possessing a large number of other desirable properties, the foundations of the industry were laid The reaction is known as vulcanisation The chemistry and physics involved in it are obscure These two discoveries made possible the transformation of raw rubber into a plastic mass, the incorporation of softeners to ease manipulation, of reinforcing ingredients, of anti-oxidants which preserve its properties, of inert materials which cheapen its products, and of accelerators which speed up the vulcanising process

The science and art of the technologist enable us to-day to produce materials presenting wide ranges of colour, density, elasticity and resilience, specific electrical resistance and resistance to abrasion, products can be made which are impermeable to liquids and gases and resistant to corrosive chemicals There are endless combinations of desirable qualities which can be brought together to serve specific purposes In a survey of the latter, however, it is necessary to distinguish between the following latex, rubber solutions, soft vulcanised products and hard vulcanised products, all these represent different physico-chemical forms of rubber

Latex is comparatively new in industrial applications, and one of the most important discoveries

in connexion with it is that the rubber can be vulcanised in its natural 'aqueous' form It is rapidly replacing solutions of raw rubber in coal-tar naphthas, in the treatment of tyre fabrics, in spread- and dipped-goods It is of special value in the manufacture of sponge rubbers and electrically deposited rubbers, and—looking to the future—its use as a binder, either as a main or auxiliary material, bids fair to penetrate far and wide in industry.

The common solvent for raw rubber is coal-tar naphtha Solubility is increased by previous mastication of the rubber, though this treatment decreases subsequent adhesive properties Uses here lie chiefly in the field of adhesives and fabric proofing

If the process of vulcanisation is carried out in the presence of excess sulphur, vulcanite or ebonite (hard vulcanised rubber) is produced The two main fields of application are electrical insulation and corrosive resistant goods, such as linings for conveyors, storage tanks and pipes

There remain the soft-vulcanised products, and it is in this category that rubber displays its amazing versatility. Its applications are literally too numerous to mention

A rough index of proportionate industrial absorption of rubber based on American data is approximately automobile industry 80 per cent, footwear industry 9 per cent, electrical industry 1 per cent, fabrics 1 per cent, surgical goods 0 5 per cent and the balance in toys and novelties, floorings, etc

Of the fundamental problems concerned with the constitution of the rubber hydrocarbon molecule, the process of vulcanisation, now almost a century old, the action of accelerators and the colloidal system presented by rubber-latex, relatively little is known, and it is surprising that the technologist has been able to advance so far without more aid from fundamental research. That his advance has been substantial is a matter of universal experience, but he who would make his experience more intimate and widen his knowledge of a young industry with great potentialities, will find profit in a visit to the Rubber Exhibition at the Science Museum, South Kensington

This exhibition is a very comprehensive one, and its sponsors have met with a full measure of success in their efforts to make it educative. A wide field is covered from the planting of the *Hevea* seed The exploitation of the bark, the processing of latex to produce plantation grades of raw rubber, the milling and compounding of the latter to produce articles of everyday use, are shown It is not possible to deal more than briefly with the general sections of the exhibits

The plantation section shows the lay-out of an estate and the work involved in good husbandry, the prevention of soil erosion, measures of prophylaxis against disease, the economic tapping systems and the operations involved in re-stocking, by the propagation of pedigree buddings An exhibit of particular interest to the layman is the display of latex, since, while it was recorded as long ago as 1781 that this material could be preserved by the addition of certain alkalis, it was not until 1920, when bulk shipments were sent in the ballast tanks of steamers from Sumatra to America, that it became important industrially. How important it is now will be evident when the visitor sees rubber-thread, sponge rubber and dipped goods made from it

The manufacturing section, besides showing the latex applications, shows the machinery for milling, compounding and vulcanising in actual operation.

The scientific section is of special merit in demonstrating the varied contributions of science to the development of the industry Demonstrations are staged showing the Brownian motion of the latex globule and its movements in an electrical field, the technique involved in dissecting the rubber globule, operations of creaming, centrifuging, homogenising and coagulating The student technologist can revel in plastometers, viscometers, durometers, etc He will be attracted by an ingenious device demonstrating the relative activity of various accelerators He will be able to inspect a Wiegand's pendulum and demonstrate to himself the Joule effect He should take this unique opportunity to inspect a well-arranged, though congested, set of valuable instruments and apparatus.

The section dealing with applications ranges from the service of the product in the automobile industry to almost the complete fitments of a surgical theatre

The historical section contains the original plaster study of the bust of Sir Henry Wickham, seeds of the original collection made by him in the Amazon basin, and such interesting exhibits as Hancock's experimental machinery.

There is one inconspicuous exhibit of special interest to the research worker This contains expanded chlorinated rubbers, oxidation products of rubber, and a variety of new products which touch the fringe of what must be a field of great possibility, namely, the use of rubber as a raw commodity for the manufacture of other substances. In this connexion, we have recently learned that rubber is amenable to hydrogenation.

Exhibitions of this nature are very difficult to organise, and the best-organised of them can be prodigal of a visitor's time. To minimise this, the sponsors have made available a carefully indexed guide. This reaches a high standard and the visitor will find it very informative and almost indispensable

International Union of Pure and Applied Physics

REPORT OF THE COMMISSION OF SYMBOLS, UNITS AND NOMENCLATURE

IN 1931, the International Union of Pure and Applied Physics appointed a commission consisting of Profs Keesom, Kennelly and Fabry under the chairmanship of Sir Richard Glazebrook, with Dr Ezer Griffiths as secretary, to deal with the general questions of symbols, units and nomenclature. This Commission submitted its report to the General Assembly of the Union at its meeting in London on October 5 last, and the following resolutions were authorised for publication.

THE STANDARD THERMAL UNIT

(1) The unit of heat when measured in units of energy shall be the Joule, defined as equivalent to 10^7 ergs

(2) The gram-calorie is the amount of heat required to raise the temperature of one gram of water from 14 5° to 15 5° of the International Scale of Temperature under normal atmospheric pressure

As a note on recommendation (2), it is stated that according to existing measurements, the gram-calorie is equivalent to 4 18_5 Joules, and that pending a decision by the International Convention of Weights and Measures as to the relation between the International and the C.G.S. electrical units, the value of the International Watt Second may be taken as 1 0003 Joules.

ELECTRICAL AND MAGNETIC UNITS

The accompanying table was accepted as defining the units in terms of which the electromagnetic quantities required for practical purposes are measured.

TABLE 1 ELECTROMAGNETIC UNITS

Quantity designated	C.G.S. units			Practical units in terms of	
	Symbol	Defining equation	Name	C.G.S. units	Volt-ampere units
Flux	Φ	$\frac{d\Phi}{dt} = -E$	Maxwell	10^8 Maxwells	Volt second
Magnetic Induction or Flux Density	B	$\int B\,dS = \Phi$	Gauss	10^8 Gauss	Volt second per cm²
Magnetomotive Force round a circuit	F	$F = 4\pi NI$	Gilbert = Oersted cm	10^{-1} Gilbert	$1/4\pi$ ampere turn
Intensity of Magnetising Field	H	$\int H \cos\epsilon\, dl = F = 4\pi NI$	Oersted	10^{-1} Oersted	$1/4\pi$ ampere turn per cm of path of H
Permeability	μ	$\mu = \frac{B}{H}$	Permeability*	$\frac{10^8 \text{ Gauss}}{10^{-1} \text{ Oersted}}$	Volt second per cm² / $1/4\pi$ ampere-turn per cm length of path of H

* The unit of 'permeability' on the C.G.S. system is the *permeability of free* space—in practice that of the air This unit has received no special name The statement that the permeability of a given medium is μ implies that it is μ times the permeability of free space

Complete agreement as to the definitions of B and H has not yet been reached For the definition of B we are not far from it, but the definition of H still remains somewhat uncertain If in the future, definitions should be adopted which would imply that B and H are quantities of the same kind, Table 1 would still hold It would then be understood that the names Gauss and Oersted were two different names given to the same quantity determined by experiment In these circumstances either one or the other of the two synonymous words might be employed as found more convenient.

In the report mention is made of the decisions of the International Electrotechnical Commission at its meeting in Paris in 1933, one of which was the statement that the formula $B = \mu_0 H$ represents the modern concepts of the physical relations for magnetic conditions *in vacuo*, it being understood that in this expression μ_0, the permeability of free space, possesses physical dimensions

In the case of magnetic substances, the above formula becomes $B = \mu_1 H$, in which μ_1 has the same dimensions as μ_0. It follows that the specific or relative permeability of a magnetic substance is a number equal to μ_1/μ_0

As a consequence of this, the International Electrical Commission recommended that the symbol μ_0 should be introduced into certain formulæ employing magnetic units

The report also includes a number of appendixes dealing with the basic definitions of the system of electrical units, alternative methods of definition; the resolutions adopted by the International Electrical Commission at Oslo in 1930, and the Giorgi system, in which the metre and the kilogram replace the centimetre and the gram in the system of fundamental units, whilst the ohm is taken as the fourth There is also a supplement by Prof Abraham entitled "Note sur ce que pourraient être les définitions des grandeurs magnétiques", which has been prepared by him in response to a request made at a meeting in Paris in July 1932.

THERMODYNAMIC SYMBOLS

The Commission in its report points out the diversity of practice as regards thermodynamic symbols, and is of the opinion that it is desirable to make an effort to remedy the existing confusion

The following resolutions were accepted by the General Assembly.

(1) That Table II be put forward for the National Committees as a satisfactory series of symbols and nomenclature for the thermodynamic quantities referred to, and

(2) That E, φ and I be accepted as alterna-

tive symbols for Internal Energy, Entropy and Heat Content respectively.

(3) That thermodynamic quantities should always be expressed in the Centigrade scale of temperature.

TABLE II SYMBOLS FOR THERMODYNAMIC QUANTITIES

Name	Entropy	Internal Energy	Free Energy	Thermal Potential or Gibbs' Function	Heat Content or Enthalpy	Work
Formula	—	—	$U - TS$	$U - TS + PV$	$U + PV$	
Symbol	S or φ	U or E	F	G	H or I	W

In the above formulæ, P and V should be interpreted as representing a generalised force and generalised co-ordinate respectively

FUTURE WORK OF THE COMMISSION

Consideration was given to the policy which should govern the future activities of the Commission and its relationship to those other international bodies which deal, among other matters, with the definitions and nomenclature of their subjects

The International Union of Pure and Applied Physics decided that the S U N Commission might usefully continue to work ·

(1) By co-operating with existing international bodies in the preparation of glossaries or lists of definitions with the view of making them more useful to physicists in general

(2) By preparing, for general adoption, lists of terms occurring in two or more branches of physics.

(3) By assisting those who, in any country, are engaged in preparing such lists, with the view of bringing workers in different countries into contact and securing harmony in the results of their work

Copies of the complete report of the Commission will be obtainable from the Physical Society (1 Lowther Gardens, London, S W.7) at a price of 2*s* 9*d* in paper covers and 5*s* bound in cloth

E G

The Eider Duck (*Somateria mollissima mollissima*)

By SETON GORDON

THE eider duck, because of the handsome and striking plumage of the drake, is a familiar object off the coasts of Britain It is more numerous in Scottish than in English waters, but is plentiful throughout the year off the coast of Northumbria, where the eider is known as St. Cuthbert's duck, because of the tradition in the district that St Cuthbert, who had his cell on one of the Farne Islands, tamed the eiders of old

In Scotland the eider duck is found both east and west, and is particularly numerous during the winter months on the sheltered sea lochs on the east side of the Isle of Skye On the open waters of the Minch it is not really plentiful, nor is it often seen in winter on the open Atlantic west of the Hebrides When the eider is seen at close quarters the striking beauty of both drake and duck is apparent The drake with his black head, pale sea-green cheeks, and white breast with its faint rosy flush, is a striking object as he courts his more sober-coloured mate, but she, too, is beautiful, for a warm rosy flush is upon the rich brown feathers of her breast and back, and to relieve the monotony of her colouring there are two white bars on her wings.

The late Viscount Grey of Fallodon had an eider drake in his bird sanctuary at Fallodon for twenty-one years, and up to the last the old eider, although he was blind in one eye, delighted in courting the mallard ducks on the pond, and their rightful mates, aware that the old fellow's intentions were harmless, watched him with amused tolerance

In very early spring, sometimes even in winter, the eider drake can be seen courting the duck that has attracted his fancy Swimming round her, he raises himself on the water and utters soft cooing notes It is indeed possible that the eider remains paired throughout the year, and the late Viscount Grey told me that on seeing a large flock of eiders off the coast of Northumberland one winter day he carefully counted the sexes in the flock, and found that ducks and drakes were present in exactly equal numbers

It is a characteristic of drakes which have an 'eclipse' plumage that they take no part in the rearing of the brood, and the British eider drake is never seen near the nest In this characteristic he is different from the eider of Spitsbergen, which nests in colonies I visited some of these Spitsbergen colonies in the summer of 1921, and found the drakes on the island with the ducks, and in some instances standing guard while the ducks brooded their eggs. The drakes may have kept off the Arctic skuas which were present at most of these colonies of eiders, ready to swoop down and suck the eggs of any unprotected nest Sometimes when an eider duck left her nest, after having covered it carefully with the down which lined it, she apparently thought that her eggs would be safe from the marauding skua gulls, but the skua

on flying up, with a few swift and deft movements of the bill, exposed the eggs and made a rapid meal of them

Sealing sloops make the journey each summer from northern Norway to Spitsbergen to gather eggs and down of the eider duck The down is used for quilts, and the eggs are sold in the northern towns and villages of Norway, where the domestic hen (perhaps because of the difficulty of feeding it through the long Arctic winter) is rarely seen

The eider duck is an assiduous diver, and most of its food is taken from the floor of the ocean It is particularly fond of mussels, and the fishermen of the north-east coast have tamed eider ducks in a remarkable manner by feeding them on the mussel bait that is wasted when a sudden change of weather with rough seas, occurring after the mussels have been shelled, prevents the lines being baited with them The eider duck feeds also upon limpets, periwinkles and razor-shells, and has been known to swallow razor-shells up to ten inches long Small crabs, sea-urchins and star-fish are also eaten Eider ducks are expert divers, but they do not like a rough sea, and are not happy in turbulent breaking waves where scoter and scaup are often seen swimming and diving Eiders, both ducks and drakes, often land on some low skerry on a falling tide, and stand contentedly, dozing or preening their feathers, but the eider duck very rarely ventures above high tide-mark except during the nesting season

I do not remember having seen an eider drake at any distance from the tide except on one occasion This was early on a May morning, in the Isle of Skye. I was motoring along the main road between Portree and Kyleakin, and where the road skirts Loch Ainort and winds along the hill-face at a height of perhaps one hundred feet above the sea, I saw on the road what at a distance I thought was a seagull But as I approached I saw that this was no gull, but an eider drake, and as the car neared him he flew out over the heather-covered hillside and then out over the sea He may have been accompanying his duck in a search for a suitable nesting place, but if the duck was in the neighbourhood she did not appear, nor did she fly away with the drake

The eider lays four to six large unspotted eggs of a greenish colour, and when she is suddenly disturbed from them she fouls her nest as she flies off, presumably to render the eggs less attractive for an animal which might otherwise make a meal off them The ducklings take to the sea on the day they are hatched, and are able to swim and dive actively They are excellent divers even from their earliest youth, and are able to survive and even to enjoy breaking waves, diving through them and keeping pace with the mother without difficulty But a prolonged period of rough and cold weather soon after they are hatched is fatal to the weaker members of the broods, and a mother eider duck may often be seen with only a single duckling following her The young ducklings have many enemies, and perhaps the most ferocious is the greater black-backed gull, which pounces down upon an unattended duckling and swallows it whole.

Obituary

PROF. CHRISTIAN HÜLSEN

WE regret to record the death of Prof Christian Hulsen, the archæologist, which took place at Florence on January 19 at the age of seventy-six years

Christian Hulsen was born at Charlottenburg and was educated at the University of Berlin, where he came under the influence of Theodor Mommsen, the Roman historian From 1882 until 1885 he studied in Italy as a travelling scholar of the Archæological Institute He returned to Berlin as a schoolmaster, but in 1887 he became a secretary of the German Archæological Institute in Rome, where he remained until his retirement in 1909 He then took up his residence in Florence and devoted the remainder of his life to writing and research

Hülsen's main life-work as an archæologist lay in the two departments of epigraphy and topography As an authority on the Rome of the classical, medieval and Renaissance periods he was without a rival, with the exception of the late Prof. Lanciani. His book on the Forum and its excavation by the Com Boni achieved a wide popularity, while for more serious students his account of the excavations on that site and on the Palatine, published in 1928, is a standard of reference Of an even more authoritative character is his "Formæ Urbis Romæ antiquæ", which is especially of value to the student for its plans of the ancient city, and its index and bibliography of the monuments. In the study of medieval and Renaissance Rome, his outstanding contributions were the publication of the Barberini codex of Giuliano de Sangallo and of the Berlin drawings of Marten van Heemskerch, the latter in collaboration with Hermann Egger His "The Churches of Rome in the Middle Ages" is a mine of valuable detailed information.

In epigraphy Hulsen's immense fund of knowledge of Roman topography served him well in compiling the inscriptions of the city of Rome for the "Corpus Inscriptionum Latinarum" In addition to his other work which appeared in book form, he was the author of a large number of contributions to archæological periodical publications in both Italian and German

Hulsen was an honorary D Litt of the University of Oxford and of Columbia University, New York, where he had delivered a course of lectures In 1917 he was appointed honorary professor in the University of Heidelberg, and shortly before his death he was informed of his election to be one of the nine honorary members of the Pontifical Academy of Arts and Archæology, Rome

MR JOHN FRASER

JOHN FRASER was born on January 31, 1854, at Newdeen, Fraserburgh, Aberdeenshire, and died in Charing Cross Hospital on January 24, 1935, from pneumonia following injuries received in a road accident

Mr Fraser was well known both as a horticulturist of high repute and as a critical student of the British flora In horticulture he received training at the old Chiswick gardens of the Royal Horticultural Society and at Kew In May 1885 he commenced work in the Jodrell Laboratory, Kew, for Sir John Lubbock, afterwards Lord Avebury, and the connexion thus established lasted for many years Fraser was responsible for much of the detailed work underlying Lord Avebury's classical researches on seedlings, pollen, buds, stipules and other botanical subjects He also edited or contributed to many well-known horticultural publications

As a field collector and observer and a herbarium investigator, Fraser was held in high esteem by a wide circle of botanical friends In his later years he specialised on the taxonomically difficult genera *Mentha* and *Salix*, and his published accounts of these genera give evidence of a clear logical mind and considerable ability in concise description His fine herbarium collections of about nine thousand sheets, together with his manuscript notebooks, have been presented, at his written desire, to the Royal Botanic Gardens, Kew, by members of his family There are many valuable Scottish gatherings among his specimens, and the flora of Surrey is particularly well represented His collection of seedlings of British plants, numbering several hundred sheets, must be unique, and will be of great value in future investigations of life-histories

Fraser was elected a fellow of the Linnean Society in 1889, and the Council of the Royal Horticultural Society conferred on him the Victoria Medal of Horticulture in 1922 and the Veitch Memorial Medal in 1929

W B TURRILL

WE regret to announce the following deaths

Mr Eric H S Bruce, editor of the *Aeronautical Journal* in 1899 1908, well known for his work in aviation, especially on balloons, kites and airships, on February 28, aged eighty years

Prof William Duane, professor of biophysics in Harvard University since 1917, an authority on radioactivity and X-rays and their application to the treatment of disease, aged sixty-three years

Mr W J A Grant, a member of several Arctic expeditions, after whom Cape Grant in Alexandra Land was named, on March 10, aged eighty-three years

News and Views

A British Magnetic Survey Vessel

THE explanatory statement by the First Lord of the Admiralty, which was presented with the Navy Estimates for 1935 to the House of Commons on March 6, contained the interesting information that it has been decided to construct a magnetic survey vessel A first instalment of £10,023 towards the construction of this vessel has been included in this year's estimates The unfortunate destruction by explosion and fire of the *Carnegie* on November 29, 1929, while in harbour at Apia, Western Samoa, brought the valuable work which had been carried on by this vessel to a sudden conclusion Constructed for, and maintained by, the Carnegie Institution of Washington, she had in six cruises between 1909 and 1921 traversed 252,702 nautical miles in 3,267 days actually at sea Of the seventh cruise of 110,000 nautical miles, nearly one half had been completed upon the arrival of the *Carnegie* at Apia, this cruise was planned particularly with the view of determining magnetic secular variation

THE magnetic charts published by the British and other Governments for use at sea have been based in recent years to an increasingly large extent upon the data provided by the *Carnegie* There are some serious gaps in the present data, which would have been filled if the *Carnegie* had completed her last cruise Due partly to these gaps and to a recent rapid change in the secular variation in the Indian Ocean, the extrapolated values of the magnetic elements in the southern Indian Ocean are now unreliable, and the possibility of serious errors in this and other areas in future charts has given rise to some concern. The Carnegie Institution, having definitely decided not to replace the *Carnegie*, and in view of the special interest of Great Britain, as the principal maritime nation, in the accuracy of the magnetic charts, the British Government has assumed the responsibility A non-magnetic ship is to be constructed, primarily for the purpose of determining magnetic data at sea Details of the design have not yet been decided upon, though it is probable that the new vessel will be larger than the *Carnegie*

Refugee Scholars

A PAMPHLET entitled "A Crisis in the University World" issued last week by the High Commissioner for Refugees from Germany (obtainable free of charge from the General Secretary, Academic Assistance Council, Rooms of the Royal Society, Burlington House, W 1) gives an account of the assistance to displaced German scholars and men of science during the past two years. Approximately 650 of the

university teachers dismissed have left Germany. Of these, 248 have been permanently re-established, 131 in Europe and 117 outside Europe, 366 others have been given temporary assistance which has enabled them to continue their studies in universities or other institutions Most of this work of academic assistance has been carried out by special emergency committees in Europe and the United States, which have succeeded in raising a quarter of a million pounds for the purpose of creating special positions in universities and research centres for the refugee scholars Nearly £69,000 has been specially raised in Great Britain for the assistance of the refugee scholars 40 have been permanently re-established and 170 have been given temporary hospitality In addition, the Academic Assistance Council has been recognised as the international information centre by the High Commission for Refugees The pamphlet outlines the plans of the academic committees for the future, it states that a constructive solution of the problem is possible and that the task undertaken by the committees is manageable, provided that there is sufficient financial support

Academic Assistance Council

A PUBLIC appeal for funds has been made by the Academic Assistance Council to enable it to continue its work The appeal is signed by Mr Stanley Baldwin, Viscount Cecil of Chelwood, Mr Winston Churchill, the Earl of Crawford and Balcarres, the Marquess of Crewe, Viscount Halifax, the Marquess of Londonderry and Lord Meston, in their private capacities as members of the university world and not officially as chancellors of British universities The Council needs funds with which to continue emergency grants in aid to approximately seventy of the displaced German scholars for a period of not more than two years, and also for the creation of twenty special research fellowships of a more permanent character It is essential also that the Council shall be enabled to continue its important work as an information centre and its investigations throughout the world for new positions in which the temporarily assisted scholars may be placed on a self supporting basis The Academic Assistance Council has, from the start, emphasised the issues of principle implicit in its work; it has not confined its activities to the displaced German scholars alone The great importance of the research which the Council has been able to salvage has been demonstrated from time to time during the past two years in our own columns and in those of other scientific journals As a research subsidising organisation, the Council has, indeed, an impressive record and merits continued support. Donations, subscriptions or bequests should be sent to Lord Rutherford, president, Academic Assistance Council, Rooms of the Royal Society, Burlington House, W.1; cheques should be made payable to the Academic Assistance Council.

Col. Crompton's Ninetieth Birthday

THE many friends of Col. R E. B. Crompton, F.R.S., are organising a banquet to be given in his honour on May 31, which will be his ninetieth birthday At this banquet he will be presented with his portrait, and he has signified that his intention is to present it to the Institution of Electrical Engineers Col Crompton has had a wonderful life He still talks about the Great Exhibition in Hyde Park in 1851 as if it were an affair of yesterday At the age of eleven, he enrolled as a cadet in the Royal Navy, and before reaching the age of twelve received the Crimean War medal and Sebastopol clasp In 1864 he was gazetted into the Rifle Brigade, and did much for road transport in India by helping to substitute road engines for bullock trains He began work as an electrical engineer in a small way at Chelmsford in 1878, but in 1881 at the Paris Exhibition he gained the first gold medal ever given for electric lighting plant In 1886 we find him, with the warm approval of the Emperor Francis Joseph, supplying the Opera House in the Ring Street in Vienna with the electric light; and he soon found it necessary to open a branch in Vienna He took a leading part in the South African War, designing traction engines fitted with dynamos and portable searchlights He also saw much active service During the War of 1914-18 he did very valuable work in connexion with 'tanks' He has always had an unflagging interest in motor vehicles and in the adaptation of roads for their use Those who use our highways owe him a deep debt of gratitude He has been a member of the councils of the Institutions of Civil and Electrical Engineers longer than anyone else.

Prof. Norbert Wiener

PROF. NORBERT WIENER, professor of mathematics at the Massachusetts Institute of Technology, has accepted an invitation to join the faculty of the National Tsing Hua University in Peiping, China, as research professor of mathematics for the next academic year. Prof Wiener expects to sail for China next July Dr Wiener's outstanding contributions in the field of higher mathematics have brought him wide recognition Last April he was elected to membership of the U S National Academy of Sciences, and in 1933 he was a joint recipient of the Bocher prize given by the American Mathematical Society for notable work in mathematical analysis He is a member of the London Mathematical Society, and in 1931–32 served as lecturer at the University of Cambridge He has carried on advanced studies at Cornell, Columbia, and the Universities of Cambridge, Göttingen and Copenhagen He joined the staff of the Massachusetts Institute of Technology in 1919 and in 1932 was appointed to full professorship The National Tsing Hua University is maintained by indemnity funds following the Boxer rebellion, which were returned to China for educational purposes by the United States. From time to time the University entertains men eminent in various academic fields as visiting members of its staff Among them have been Prof. George D. Birkhoff of the mathematics department at Harvard, the Indian poet and philosopher, Rabindranath Tagore, Bertrand Russell, the French mathematician, Hadamard, and the French physicist, Langevin

Max Oertel

MAX JOSEF OERTEL, one of the most eminent and versatile German physicians of the second half of the nineteenth century, was born at Dillingen in Bavaria on March 20, 1835. He first studied under Prof von Pettenkofer at Munich, where he made a considerable number of analyses of the air in various public institutions and private houses which he published in a work entitled "Experiments on the Accumulation of Carbonic Acid in Inhabited Localities" Afterwards he devoted himself to the study of diseases of the throat, including diphtheria, on which he published some of the most important articles on the causation of the disease prior to the discovery of the Klebs-Loeffler bacillus His other works on diseases of the throat were concerned with tumours of the larynx, instruction in laryngology, and treatment of respiratory affections Oertel was the first physician in South Germany to lecture on laryngology, and was appointed extraordinary professor of laryngology at Munich in 1876, which office he held until his death on July 19, 1897. He was also well known as a general physician and particularly for his treatment of diseases of the heart, in which he paid special attention to diet and exercise.

Award of the Duddell Medal to Dr. W. E. Williams

THE council of the Physical Society has awarded the twelfth Duddell Medal to Dr W Ewart Williams, lecturer in physics at King's College, London, who is distinguished for his work in optical design, chiefly in the region of interferometry The Medal is given to "persons who have contributed to the advancement of knowledge by the invention or design of scientific instruments, or by the discovery of materials used in their construction". The principal invention of Dr Williams is that of the reflection echelon spectroscope. The basic idea of such an instrument was described by the late Prof Micholson nearly forty years ago, but its practical construction seemed impossible until the discovery by Williams that two optically plane surfaces of quartz or fused silica could be placed in permanent optical contact without exerting the mechanical force needed with glass surfaces He saw that a number of fused silica plates of exactly equal thickness could be built up in the necessary echelon formation without introducing any distortion that would ruin the optical performance of the instrument The reflection echelon is the only form of spectroscope of sufficient resolving power which can be used in the ultra-violet part of the spectrum, where, in a number of cases, lie the lines of greatest interest from the point of view of 'fine structure', a detailed study of which gives us information about the structure of the nucleus in its normal state.

BY adding two small mirrors to the echelon and mounting it in an evacuated chamber, Dr. Williams has adapted the instrument, originally meant for fine-structure work only, for the accurate measurement of the wave-lengths of the lines. In consequence of the far greater resolving power now available, the wave-lengths of the lines can be measured with a corresponding greater degree of accuracy, and the method of calculation is far simpler and more rapid than with the Fabry-Perot interferometer He has also devised a method of standardising the metre in terms of wave-lengths by means of the reflection echelon This permits the number of wave-lengths contained in a gauge of approximately a metre length to be determined in two operations, as distinct from the numerous stages involved in the present methods The principle of the reflection grating has been also applied by him to directional aerial systems for short-wave wireless transmitters, which are being used in America, and he has improved a number of optical instruments, amongst which are the Rayleigh refractometer and (in conjunction with Mr. F. Twyman) the Fabry-Perot interferometer.

National Inland Water Survey

IN the discussion which followed the reading of Dr Brysson Cunningham's Paper on National Inland Water Survey, a summary of which appears on p. 443 of this issue, Vice-Admiral Sir Percy Douglas, the chairman of the British Association Research Committee on the subject, described the work of the Committee subsequent to the date of the reception of the deputation by the Minister of Health, and expressed the gratification which he felt at the unanimous agreement of the members of the Committee on a draft outline of the scope of the survey which had been drawn up and forwarded to the British Association, and which he hoped would be recorded in the *Geographical Journal*, for which purpose he read the several items Dr H R Mill spoke of the association of the Royal Geographical Society with water survey, and alluded in particular to the observations made on the Exe and the Medway with which he had been connected Sir Henry Lyons, chairman of the new Survey Committee, welcomed the interest taken in the matter, and said that as his Committee had only just met quite recently for the first time, it would be premature at present for him to express any views on the course of action which he and his colleagues might decide to take Capt W. N McClean described the more important features of River Flow Records, and showed how he had built up an organisation which he considered might be of great assistance in the work of river and stream gauging. Mr. G. J. Griffiths, chief engineer of the Thames Conservancy Board, emphasised the value of river flow records and the advantage which had accrued from having prolonged observations at Teddington and elsewhere; he considers a national survey to be long overdue. Dr. Bernard Smith dealt with the importance of observations relating to underground water and the necessity of prosecuting researches thereon in all practicable directions.

Preservation of Sites of Scientific Interest

THE British Association has recently been receiving from the Ministry of Health information of all schemes in progress under the Town and Country Planning

Act, in order that if any of these should disclose any risk of the destruction of sites or objects of scientific interest, representations may be made on behalf of the Association to the planning authorities and to the Ministry. In addition to natural features, or possibly buildings, which may be worthy of preservation on scientific grounds alone, it is clear that there must be many areas worthy of protection on grounds of amenity, and at the same time of sufficient scientific interest, whether geological, botanical or otherwise, to justify adducing arguments from the side of science in their favour. The first step taken by the Council of the Association was to communicate with all the local societies in correspondence with the Association, inviting their attention to the subject of planning and asking for information on any instances in which the Association might usefully take action; only a few have as yet come to hand. The whole subject will come under consideration at the Norwich meeting of the Association, when it will be dealt with by Prof. P. G. H. Boswell in an address as chairman of the Conference of Delegates of Corresponding Societies. Meanwhile the Council has appointed a panel of some sixty prominent members representative of geology, geography, botany and zoology, any of whom may be called upon for advice in connexion with proposals for preservation, and all of whom have been asked to bring to the notice of the officers any examples which may have come under their personal notice.

Roman Villa near Lydney

A NEW Roman villa on the River Severn near Wollaston, between Lydney and Chepstow, of which the discovery and partial exploration is described in *The Times* of March 8, illustrates the perennial character of the human response to an enduring need. A fire-platform and lighthouse in alignment mark the channel through the Guskar Rocks guarding the creek, on which the villa is situated, in a manner which might stand in a modern sailing direction. Before the examination of the site the existence of the creek, which had silted up, was indicated only by a stream in a depression; but evidently it must have been, with Lydney harbour, a port of call of importance, probably in relation to the iron-workings of Ariconium (Weston-under-Penyard) to the north. In any event, the villa with its sea-frontage was not only the centre of a wide settlement, still unexplored, but it is remarkable also for the unusual amount of iron it has yielded among its relics. The earlier villa, upon which a second was superimposed, was erected about A.D. 130 in the reign of Hadrian. It stood about 250 yards from the shore. It was of considerable size and contained nine rooms and a corridor and had a bath system along the sea front. One hundred and seventy years later it was destroyed, possibly, it is thought, by an Irish raid. After a lapse of twenty years, the second, a smaller building, was erected. It contained only four rooms, but it also had a bath system. This villa lasted for about a century. The details of the buildings and the associated relics have provided a number of noteworthy features, and the further examination of the site, which depends, as usual, upon funds being raised, will undoubtedly well repay the expenditure of time and money.

Irish Folk-lore

THE appointment by the Irish Free State of a Commission on Irish folk-lore is an extension of the active interest already shown by the authorities in the antiquities and history of Ireland that will be welcomed by all students of her traditions and ancient culture. The Commission is to be comprehensive in scope. It will arrange for the collection, collation and cataloguing of both oral and written folk-lore material, and also, if thought desirable, for the publication of such material. The scheme for collection which has been drawn up includes provision for a body of collectors who will travel through the country for the purpose of taking down by means of recording machines not only tales and songs, but also, among the older members of the community, their recollections of life in the country-side in their young days. Subject to the approval of Dail Eireann, a sum not exceeding £3,250 a year, for a period of five years, will be devoted to the work of the Commission. Although Ireland, in comparison with other parts of the British Isles, has not been badly served in the matter of attention from the collector of local lore and legends, it has always been known that extensive tracts of tradition and custom remained untouched, and notwithstanding the sophistication which has affected Ireland in common with other countries of recent years, the remoter districts still retain much of their primitive character and tradition. In addition to its work of collection, the Commission's activities will afford an opportunity for that systematic treatment of the material for which adequate opportunity has not hitherto been available, but which in dealing with conditions in Ireland is highly desirable.

British Museum Acquisitions

AMONG the notes on recent acquisitions by the British Museum in the *British Museum Quarterly*, 9, No. 3, particulars are given of sources from which came part of the sum required to make up the initial payment for the Eumorfopoulos collection of Chinese and Far Eastern art, and progress is reported in the allocation of the collection to Bloomsbury and South Kensington. A contribution of £5,000 was received from the National Art Collections Fund, £5,000 from Sir Percival David and £1,000 from the Universities' China Committee in London. The bequest to the British Museum and the Victoria and Albert Museum of three quarters of the residue of the estate of the late J. R. Vallentin for the purchase of works of art for the two museums was also allotted to this use. It is stated that the collection is so large that it will be possible to place a certain number of pieces on loan in some of the leading provincial museums. When, however, the scheme for a Museum of Oriental Art comes into being, it is intended to recall these loans, and the whole collection will be brought together again to form an important part of what, it is hoped, will be the finest museum of oriental art

in existence Parts of the collection already have been, or are in course of being, described, but accounts of special classes of exhibits are to be prepared and published from time to time Among other notes in this issue of an interesting publication which is not so widely known as it deserves, is an account of the fragments of the unknown gospel acquired last summer, to which Mr H L Bell has recently directed attention in *The Times*, and descriptions with illustrations of an Egyptian wax figure which, if it be, as is thought, a model for making moulds for casting bronze figures, is indeed rare, and some unique objects of a varied nature from Roman London

Empire Cotton Growing Corporation

AT a meeting of the Administrative Council of the Empire Cotton Growing Corporation held in Manchester on February 7, the resignation was received of Mr Milligan, who has been the Corporation's senior representative in Africa since 1924 During this time he has travelled constantly about South Africa and visited in addition the Corporation's staff in Swaziland and Rhodesia He has been succeeded by Mr Parnell, who has long been associated with the Corporation's work in South Africa The Council received the report of Mr May, assistant secretary of the Corporation, upon a tour he had recently made in East and South Africa, particularly with reference to developments in Tanganyika Territory At many places in this territory, the Corporation's assistance will be used towards developing an interesting scheme, evolved by the Agricultural Department, for native holdings on which cotton will be grown in a system of mixed farming Each family will be given the freehold of their holding, which will consist of 20 acres Of these, 10 acres will be reserved for cattle grazing, and the remainder for the dwelling site and land for the cultivation of cotton and other crops The natives will also be given instruction in the preparation and use of farmyard manure

THE Mwanza area of Lake Province has hitherto produced about half the cotton grown in Tanganyika The organisation of its seed supply is therefore a matter of importance, and with the help that is now being given by the Corporation it is hoped to put this on a satisfactory basis The selection of the best strains will be carried out at the Experiment Station at Ukiriguru, these will then be multiplied in the special area that is being provided for the purpose, just across the arm of Lake Victoria known as Smith Sound. The seed from this area will be bulked on an island in the Lake, which makes an admirable isolated area where admixture of the strains can be prevented. The bulked seed will then be distributed in the following season throughout the Lake Province.

Forest Research in the Malay States

THE annual report of the Forest Research Branch, 1933, is issued with the "Report on Forest Administration for the year 1933 of the Federated Malay States" (a Supplement of the *F.M.S. Government Gazette*, June 15, 1934. F.M.S. Government Press). Research, under which is included education, has made considerable progress in the Forest Department of the Federated Malay States A Forest School has been started much on the lines of the Rangers' School at Dehra Dun, India, which has nearly half a century of good work behind it. The practical courses of the Malay School during the year under view included a forest reconnaissance in mountainous jungle in the State of Perak, it served the excellent purpose, among others, of acquainting the students with commercial tree forms not normally encountered in the lowland forests An area of 2,400 acres of this hill forest in the Bubu reserve was explored and the enumeration work was conducted on more intensive lines than hitherto, both as regards composition of the crop and the possibility of commercial exploitation This appears an excellent departure and the experience thus gained should be invaluable to all, whilst the work achieved will be of practical value Research work is being carried on in sylviculture, where some interesting research work is being achieved, botanical, wood technology, timber testing, wood preservation and forest economy generally, while zoological, chemical and meteorological problems are being studied

The National Herbarium at Melbourne

THANKS to the generosity of Sir MacPherson Robertson, a new building has just been completed in Melbourne for the housing of the National Herbarium collections, and the transfer of material is in progress The building is a block, approximately 100 ft by 80 ft, containing two floors On the upper floor provision is made for the collections (numbering some 1,500,000 sheets) and for a library of more than 10,000 volumes On the lower floor are a museum of economic botany, a laboratory, a lecture hall and the administrative offices The construction is fire-proof throughout, all cabinets are of steel and the main door is guarded by fire-proof devices operating automatically when the temperature reaches a certain point The collection was commenced about 1856 by the late Baron von Mueller, and it is intended to preserve the existing division into two sections (i) Australian and (ii) extra Australian The former is very complete and contains a number of type specimens The room allotted to it is 60 ft by 35 ft, allowing for 30 per cent expansion, or 55 per cent if further cabinets be installed The extra-Australian section, which is already extensive and is continually growing by exchanges, will be housed in a room 80 ft. by 35 ft

Sounds made by Fishes in the East Indies

IN NATURE of November 17 (p. 769), we quoted an interesting account of sounds heard in the East Indies by Capt. P Jansen. We have received a letter from Dr. J. D. F. Hardenberg, of the Laboratory for Investigation of the Sea, Batavia, with reference to this note He states that the comparison of these noises with the sounds made by foghorns is quite correct They remind one also of the sounds made by motor traffic on a busy thoroughfare when heard at a distance of about a hundred yards. The noises, however, do not proceed from the earth, but are

made by fishes of the genus *Therapon*, as described by Dr. Hardenberg in a recent paper (*Zöol Anz*, 108, 1934) The other sounds mentioned by Capt Janson have also been heard by Dr Hardenberg, though less frequently, and once, when in the Java Sea, he heard sounds as if made by silver bells Their origin is still unknown, but he supposes that they are also made by animals.

American Society for Testing Materials

It is a great help to industry to have standard specifications for the materials used in commerce, and to have methods of testing to find out whether the materials offered for sale come up to the standard or not In Great Britain the British Standards Institution (B S I) of 28 Victoria Street, S W 1, publishes standard specifications and gives also the methods of testing These have been passed by committees consisting of engineers, manufacturers, Government officials and all interested in securing raw materials or finished products of the best quality If experience shows that the methods used are ineffective, then the old committee meets again or another committee is formed and it brings out a revised specification In the United States, the American Society for Testing Materials (A S T M) performs similar functions The *Proceedings* of this Society are issued annually, and give reports by committees and the 'tentative' standards adopted Each of the annual volumes contains about 2,000 pages. In the 1934 volume such subjects as vapour lock of petrol, creep tests and data, soil testing methods, rubber raw materials, etc, are discussed Twenty-one of the standards appearing in the 1933 "Book of Standards" have been revised or discontinued. Fourteen of them have been revised, five of them have been replaced by new tentative standards and two have been completely withdrawn The new problems discussed will be found of interest by physicists, and open up new fields of research

Society of Public Analysts

At the annual general meeting of the Society of Public Analysts held on March 6, Dr Bernard Dyer gave an address embodying his reminiscences of the Society, from its inception to the present day. At the outset of his address, Dr. Dyer pointed out that the occasion was particularly appropriate, since it was the diamond jubilee of the Society, which held its first meeting in February, 1875, when Dr Redwood was elected president Much of the early work of the Society was concerned with food adulteration, which at that time was gross and widespread, although gradually analytical chemistry in general was brought within the scope, and in 1906 this was recognised when the title of the Society was enlarged to include analytical chemists other than public analysts. Several of the earlier presidents were well known as medical officers of health, who had also been appointed public analysts. Dr. Dyer also touched on the history of the Society in connexion with the Institute of Chemistry and the Government Laboratory, and laid stress upon the fact, that in spite of certain coolness and misunderstandings in earlier days, the most cordial relations have for many years existed between the Society and these bodies The following officers were elected for 1935 *President*, Mr John Evans, *Vice-Presidents*, Messrs L H Lampitt, S E Melling, A More, W H Roberts, *Honorary Treasurer*, Mr. E B Hughes, *Honorary Secretary*, Mr. G Roche Lynch

Hydrogen Cooling

The losses due to air friction when machines are rotating is often an appreciable fraction of the total working losses The losses can be considerably reduced by running the machines in hydrogen As the thermal conductivity of hydrogen is much greater than that of air, the temperature rise of the machine is further reduced and so it can be run at a heavier load and can therefore be rated as a more powerful machine In the *Electrician* of March 1, there is a description of a 30,000 kilovolt ampere synchronous condenser which has been built for the French Midi Railway The outer casing is built up of steel plates bolted together and designed to withstand the force of any internal explosion which might occur owing to a mixture of hydrogen and air The machine is started by a special type of transformer which only takes a quarter of full load current Tests carried out on the machine with hydrogen and air as cooling media show that the heating of the machine with hydrogen cooling was thirty per cent less than when it was run in air

The Murdoch Trust

There has been in existence for a number of years a most admirable trust, known as the Murdoch Trust, for the benefit of indigent bachelors and widowers who have done good work for science and have fallen on less prosperous days Few people seem to be aware of the existence of this Trust or of its beneficent purpose, though a modest advertisement occasionally appears, as, for example, in NATURE of March 2, p lxvi, inviting applications for donations or pensions from it We gladly direct attention to the aid thus available to persons who have promoted or helped the advancement of any branch of science and are in need. The Trustees welcome applications from scientific workers eligible for assistance from the funds they have available Particulars can be obtained from Messrs Shepherd and Wedderburn, 16 Charlotte Street, Edinburgh

Ibero-Americana Oceanographical Conference

The Ibero-Americana Oceanographical Conference was to have met at Madrid in October last, but it was found necessary to alter the date, and the assembly of the delegates was postponed until the latter part of April 1935 As at present arranged, the Conference will hold its meetings partly in Madrid and partly in Malaga Invitations to attend were sent to the Governments of the various North and South American States and to the Governments of those countries having territories in America. It is understood that the Conference will discuss

measures for obtaining oceanographical data of all descriptions in the oceans and waters adjoining their coasts, including the study of ocean currents, marine meteorology and fisheries. Having regard to the existence of the International Association of Physical Oceanography of the Sub-Committee for Oceanography of the Pacific Science Congress, however, and of various bodies dealing with marine biology and fisheries, it is doubtful whether the creation of yet another is desirable or can serve a useful purpose The General Secretary is Señor Rafael de Buen, Alcalá, 31, Madrid

New Land Speed Record

SIR MALCOLM CAMPBELL set up a new motor speed record on Daytona Beach on March 7, by obtaining a speed of 276 816 miles an hour. The previous record, also set up by Sir Malcolm, on February 22, 1933, was 272 108 miles an hour The figures for the time to cover the measured mile work out as follows first run, 272 727 miles an hour (13 20 seconds), second run, 281 030 miles an hour (12·81 seconds), average speed, 276 816 miles an hour. Sir Malcolm's car, *Bluebird*, was designed by Mr R Railton, and contains a 2,500 horse power Rolls Royce Schneider Trophy engine.

Announcements

PROF. W. N. HAWORTH, director of the Department of Chemistry, University of Birmingham, was elected a corresponding member of the Bavarian Academy of Sciences on February 16

THE Bessemer Gold Medal for 1935 of the Iron and Steel Institute has been awarded to Prof. A M Portevin, director of the Institut de Soudure Autogène, professor at the Ecole Supérieure de Fonderie, and at the Ecole Centrale des Arts et Manufactures, Paris

THE D'Arsonval prize has been awarded by the Société française d'électrothérapie et de radiologie to the Belgian physician Dr Etienne Hubert Henrard, for a thesis on "Short Hertzian Waves and their Medical Applications".

PROF H LEVY will deliver a lecture on "Science and Social Responsibility" before the Institution of Professional Civil Servants on March 22 in the lecture hall, Royal Society of Arts, John Street, Adelphi, W C 2 The chair will be taken by Mr H T Tizard. Tea will be served at 5 p m and the chair will be taken at 5 30 p m Admission is free and tickets of admission are not required.

THE Royal Society of Arts has recently announced the subjects for the Thomas Gray prizes to be offered in 1935. One prize of £100 will be awarded for an "invention, publication, diagram, etc, which is considered to be an advancement in the Science or Practice of Navigation". The other prize will be awarded for the best essay on "Modern Navigational Appliances." Further information can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, London, W C 2

THE following appointments have recently been made by the Secretary of State for the Colonies. Mr H. Atkinson, to be deputy Government analyst, Ceylon, Mr. J R. E Hindson, inspector of plants and produce, to be assistant superintendent of agriculture, Gold Coast; Mr A H Malpas, assistant marine biologist, to be director, Colombo Museum, and marine biologist, Ceylon; Mr D B Sabiston, deputy superintending produce inspector, to be superintendent of agriculture, Nigeria

AT the annual general meeting of the Institute of Metals, held on March 7–8, the following officers were elected for 1935. *President*, Dr H Moore; *Vice-Presidents*, Mr. W R Barclay, Dr C H Desch, Dr A. G C Gwyer, Prof D Hanson, Mr H C Lancaster, Mr E L Mercom, *Honorary Treasurer*, Mr John Fry

THE Royal Astronomical Society is prepared to issue (provided sufficient support is forthcoming) a third edition of the Franklin-Adams Chart of the Sky, in 206 sheets, each covering an area 15° × 15° The Chart is in three sections (1) North Pole to Dec + 22°, (2) Dec + 22° to − 22°, (3) Dec − 22° to South Pole The price of the complete set, in three cases, has been fixed at £27, including carriage. Should any desire one or two of the sections only, subscriptions will be received for the part required at a corresponding rate Further particulars, and application forms, may be obtained from the Assistant Secretary, Royal Astronomical Society, Burlington House, London, W.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A temporary assistant engineer in the Headquarters Offices of the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S W 1 (March 18) A lecturer (woman) in biology and nature study in the Saffron Walden Training College, Essex—The Principal (March 22). A lecturer in physiology, an assistant lecturer in mathematics, and an assistant lecturer and demonstrator in housecraft at Brighton Technical College—The Secretary, Brighton Education Committee, 54 Old Steine, Brighton, 1 (March 29) A lecturer (woman) in biology and natural history in the Diocesan Training College, Derby—The Secretary (April 1). A professor of physiology in the King Edward VII College of Medicine, Singapore—The Director of Recruitment, Colonial Service, 2 Richmond Terrace, Whitehall, London, S.W 1 (April 8) Two lecturers in mechanical engineering at the Lester Technical Institute, Shanghai—The Lester Trust, c/o Messrs. Viney, Price and Goodyear, Empire House, St. Martin's-le-Grand, E.C 1 (April 8) A chief mining engineer for the Northern India Salt Revenue Department—The High Commissioner for India, General Department, India House, Aldwych, W.C 2 (April 10) Assistant keepers in zoology, entomology, geology, mineralogy, and botany in the British Museum (Natural History), London, S W 7—The Secretary (May 31).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 437.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Period of Radionitrogen

IN their first communication on induced radioactivity, Curie and Joliot[1] reported that a radioactive isotope of nitrogen was formed from boron by bombardment with α-rays according to the scheme·

$$_5B^{10} + {}_2He^4 \rightarrow {}_7N^{13} + {}_0n^1.$$

The period was about 14 minutes and they carried out chemical tests which helped to identify the radioactive body. We[2] also investigated this reaction and found a period of about 14 minutes It was shown by Cockcroft, Gilbert and Walton[3] that this isotope of nitrogen could be formed from carbon by bombardment with either protons or deutons, but that the period in this case was about 11 minutes This latter result has been confirmed by several observers If this difference in the periods could be maintained, it would suggest a number of interesting possibilities It has, for example, been used as an argument in favour of the existence of the negative proton

The chief uncertainty in our former experiments was that, as the activation was carried out in air, we always obtained in addition radiofluorine formed from nitrogen

$$_7N^{14} + {}_2He^4 \rightarrow {}_9F^{17} + {}_0n^1.$$

Radiofluorine has a period of about 1 minute, and about half of the initial activity of the 'boron source' was due to radiofluorine It was therefore impossible to start measurements on the radionitrogen until 6–10 minutes had elapsed, and, as the total effect was always small, it was of little use to extend the measurements over more than 30 minutes.

The new experiments have been done under improved conditions, yielding larger counts, and the occurrence of radiofluorine has been almost completely suppressed by activating *in vacuo* As a result, we could now start counting 2 minutes after the removal of the boron from the source of α-rays and continue the counting for more than an hour We have counted 16,660 particles in all in seven such experiments and the periods obtained are ·

Number of Particles	Period in minutes.	Mean square error
1817	10 4	0 4
1619	11 5	0 5
1378	10 8	0 5
5220	11 3	0 2
3124	11 1	0 2
1980	10 8	0 3
1524	11 1	0 4

The final value for the period obtained by combining all the measurements is 11·0 minutes, with a mean square error of 0·1 minutes. This value is the same, within the limits of error, as that obtained for the period of $_7N^{13}$ formed from carbon, namely, 11·0 ± 1 minutes, and it seems therefore that the bodies are identical.

While we plotted the decay of the activity in the usual way, to verify that it was exponential, the above values were obtained by a computation from the observed counts in successive intervals of time according to a method developed by Dr Peierls This method is considerably more dependable than the ordinary rough graphical one, since it takes into proper account and uses the fact that the measurements are subject to probability fluctuations With the graphical method it is impossible to determine the probable error, and there may be a tendency to average the positive and negative fluctuations occurring close to each other in time, instead of striking the proper average over the whole time of measurement.

We have also carried out a rough analysis of the particles, as regards sign of charge, by means of a magnetic field, and have found no evidence of any negative emission from activated boron The results with positive and negative magnetic fields were much the same as when using activated aluminium (radiophosphorus), or, though in the reverse sense, using a very weak source of thorium C It is at present uncertain to what extent the reaction,

$$_5B^{11} + {}_2He^4 \rightarrow {}_6C^{14} + {}_1H^1$$

occurs The above result is compatible either with a small yield from this reaction or a small mass difference between C^{14} and N^{14}

We are very grateful to Dr Peierls for supplying us with full details of his method of calculating the periods

Do Whales Descend to Great Depths?

WITH reference to the letter of Mr R W Gray in NATURE of January 5, p 34, the depth to which whales may descend when diving has long been the subject of speculation

The theory that whales reach great depths is based upon observations made by whalers and others upon the length of harpoon line carried out and its apparent behaviour at the surface It is also based upon the duration of the dive, long submergence having been frequently taken to imply great depth of descent The discovery of carcasses of whales at great depths entangled in submarine cables, and stories of a similar nature, have also contributed to this theory These are in no case reliable as evidence, since there is no possible means of knowing how the carcasses reached the positions in which they were said to have been found

Apart from the fact that the length of harpoon line carried out and the apparent behaviour of the line at the surface are somewhat doubtful guides to the movements of the whale at the end of it, the

greatest caution must be exercised in deducing the normal life habits of a whale from its behaviour on being struck by a harpoon. It is probable that the whale reacts in an abnormal manner to so violent a stimulus, making, perhaps, a plunge into depths far beyond its safety limit. That this does happen seems to be indicated by the fact, mentioned by Mr. Gray, that whales have been known to die beneath the surface after taking such a plunge and have had to be hauled up, occasionally, it is said, with a broken jaw bone.

It is the depth to which a whale may normally descend during the ordinary course of its existence which is alone of interest in the present discussion, and it is doubtful whether evidence with regard to this will ever be obtainable. Those who hold that whales do not, in fact, normally descend to very great depths base their opinion on two, possibly three, considerations.

(1) It is uncertain what the effect of hydrostatic pressure would be upon an animal like a whale diving with its lungs closed. All the organs, the lungs among them, will be compressed. Some protection may be afforded to the lungs by the ribs, but it is still not far wrong to say that the lungs will be compressed to one half their normal volume at 2 atmos. pressure, to one third at 3 atmos., absolute pressure, and so on. Thus, quoting the smallest figures cited by Mr. Gray, if a whale which carries out 200 fathoms of harpoon line were actually to dive to that depth, its lungs would be compressed to considerably less than 1/35 of their normal volume. (Absolute pressure increases by 1 atmos. every 33 ft. of descent.) It seems impossible that the animal could survive anything approaching this compression.

(2) No mechanism has yet been discovered by means of which whales could avoid 'caisson' sickness on returning swiftly to the surface from great depths. The 'retia mirabilia' with which all Cetacea are provided do not seem to have any connexion with this, since they are present in seals and porpoises, which inhabit shallow waters, but can remain submerged for long periods. Their function would seem to be concerned rather with the time of submergence than with its depth.

It is possible that the great whales, owing to the high contractility of the alveolar walls and the slower circulation rate common to all large animals, are less susceptible than other mammals to 'caisson' sickness. The ductus arteriosus also remains open throughout life and may shunt off part of the pulmonary circulation. But if the physiology of the whale is in any way comparable with that of other mammals, the depth to which the animal may descend without incurring the risk of 'caisson' sickness on returning to the surface will not be enormously greater than that to which a man may descend. The safety limit for a man lies at a depth of 7 fathoms. It is possible that the safety limit for a whale might be at twice, three times or four times, even five times, the depth of that for a man, but highly improbable that it would be at 28½ times (200 fathoms) that depth.

(3) Rorqual whales in the south feed on 'krill', *Euphausia superba*. This crustacean forms dense swarms, on which the whales feed, at the surface, and is very seldom taken in quantity in plankton nets below 200 m., while the large majority are taken above 100 m. Thus there seems to be no special need for the rorqual whales, at any rate, to descend much below 100 m. during the normal course of their lives.

Sperm whales feed on cuttlefish. There is no evidence as to the depth at which these cuttlefish live. They have never been taken in nets or trawls and it has therefore been assumed, without justification, that they live at great depths.

Anomalous Scattering and Structure of Light Nuclei

THE method of analysing the anomalous scattering which has recently been developed by Wenzel[1] leads to a more detailed interpretation of the scattering phenomena, and furnishes results which so far are in excellent agreement with the other evidence available for the energy level system for light nuclei.

In Fig. 1 the lowest energy levels for a simplified nuclear model are given. The 'normal' sequence of these terms is represented by $1s$, $1p$, $1d$, $2s$, $1f$, $2p$, $2d$, $3s$ . . . etc.

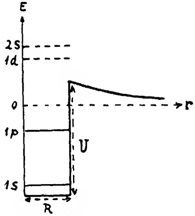

FIG. 1

The dotted levels in Fig. 1 are unstable (virtual energy levels) in the special case for which Fig. 1 has been drawn. We notice that if we deepen our potential hole U, more and more of the indicated levels become consecutively stable, and vice versa. Under the actual conditions the virtual energy levels of small positive energy determine the character of the anomalous scattering (resonance scattering).

The analysis of Pose's experiments on the collision of α-particles with protons[2] shows that the scattering is mainly due to a resonance with the virtual $1p$-level of the proton in the field of an α-particle, and thus will be described as a $1p_p$-scattering (the index p referring to a proton level).

This is in agreement with what we know about the α-particle. The $1s_p$-level is stable and occupied by two protons and two neutrons. The next level, however, is already unstable and no Li^5- and probably no He^5-nucleus is likely to exist.

If we increase the weight of the nuclei, the depth U of the potential hole is increased. Thus we must expect that in higher nuclei successively, $1d_p$-, $2s_p$- . . . etc. scattering will occur. No other experiments, however, are available at present for proton scattering.

Very similar behaviour is to be expected for neutron scattering.

If we use the model of Fig. 1 to build up the lighter nuclei (up to A[36]) from protons and neutrons, we obtain exactly the scheme proposed by Bartlett We notice, however, that for many processes this scheme has to be replaced by others which are more adequate If we deal, for example, with α-particles, it is more convenient to speak about α particle levels in the nucleus

Considering the anomalous scattering of α-particles, a similar picture to that of Fig 1 must hold (but we have naturally to account for the Bose-statistics of these particles) We give here the analysis of the anomalous α-scattering by light nuclei ·

$\alpha \rightarrow \alpha$	$1s_{\alpha}$-scattering[3]
$\alpha \rightarrow Be^{9}$	$1p_{\alpha}$-scattering[4]
$\alpha \rightarrow B^{10,11}$	$1p_{\alpha}$ scattering[4]
$\alpha \rightarrow C^{12}$	$1p_{\alpha}$-scattering[4]
$\alpha \rightarrow F^{19}$	$1d_{\alpha}$-resonance disintegration (?)[5]
$\alpha \rightarrow Al^{27}$	$1d_{\alpha}$ resonance disintegration (?)[6]
	$2s_{\alpha}$-scattering[7]

It is easily seen that this analysis of the anomalous scattering is consistent with all our knowledge about nuclear energy levels

A more complete report on this problem is to be published in the *Physical Review*

The Phenomenon of 'Wings' and the Vibrational Raman Effect in Benzene and Naphthalene Crystals

As has been pointed out in our previous note[1], the continuous spectrum (wings) observed around the primary line at the scattering of light by liquids consists of two parts The central part just near the primary line (c. 20 cm $^{-1}$ in diphenyl ether) gains in intensity when the liquid is heated, whereas the outer part remains unaltered By comparison of the Raman effect in liquid and crystalline diphenyl ether, we have shown that the later part is not due to the rotation of molecules in the liquids as usually accepted, but is produced by the vibrational Raman lines caused by slow vibrations (probably characteristic for the crystal lattice of diphenyl ether). It seemed to us of interest to include in our experiments also the crystal of benzene because the phenomenon of wings of this substance in the liquid state has been carefully studied by many observers[2].

We investigated the Raman effect of single crystals of benzene and naphthalene. The experiments have fully confirmed our previous results obtained with diphenyl ether. In place of the wings observed in liquid benzene and naphthalene, we have obtained very distinct vibrational Raman lines : $\nu_1 = 63$ cm.$^{-1}$ and $\nu_2 = 108$ cm.$^{-1}$ in the benzene crystal and $\nu_1 = 20$ cm.$^{-1}$, $\nu_2 = 38$ cm.$^{-1}$ and $\nu_3 = 94$ cm.$^{-1}$ in the naphthalene crystal The new Raman lines are indicated by arrows in Fig 1 The spectrogram showing the wings of liquid naphthalene is not reproduced, because it is similar to that of liquid benzene

The central part of the continuous spectrum just near the primary line is of great intensity in the case of liquid naphthalene, and is probably connected with existence of a very large coefficient of depolarisation of the scattered light in this substance We wish especially to emphasise that this part of the wings, the intensity of which increases on heating, is absent in the spectra of crystals (and, as it seems, in amorphous solids) and is apparently characteristic of the liquid state

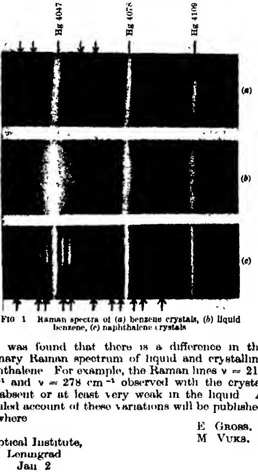

FIG 1 Raman spectra of (a) benzene crystals, (b) liquid benzene, (c) naphthalene crystals

It was found that there is a difference in the ordinary Raman spectrum of liquid and crystalline naphthalene For example, the Raman lines $\nu = 211$ cm $^{-1}$ and $\nu = 278$ cm $^{-1}$ observed with the crystal are absent or at least very weak in the liquid A detailed account of these variations will be published elsewhere

A High-Pressure Wilson Cloud Chamber

FOR various investigations, such as for large range radiation or when ionisation occurs infrequently, it is an advantage to use high pressure in a Wilson cloud chamber[1]. We have developed a Wilson chamber of 2 cm diameter in which pressure can be increased to 100 atmospheres The desired compression and sudden expansion was obtained by a piston which followed the pressure of gas in a cylinder

below the cloud chamber. By this means, a sudden expansion in the cloud chamber was more easily obtained than by the usual mechanical means of moving a piston.

At 80 atmospheres of nitrogen saturated with water vapour, the practicability of a high-pressure Wilson chamber was confirmed. We found that for an expansion ratio of only about 17 per cent, condensation occurred in an ionised atmosphere (radioactive material was brought near the chamber), for a greater expansion ratio a general cloud was always present, and for a smaller expansion ratio no visible condensation occurred even in the presence of strongly ionising substances.

We are now constructing a Wilson chamber of 8 cm. diameter to continue investigations which were suggested by the satisfactory preliminary results obtained with the apparatus just described.

Plea for the Preservation of a Scientific Library

THE object of this letter is to avert the threatened dispersal of a unique scientific library with historic associations.

Stephen Peter Rigaud, the most eminent historian of British science of his day and professor of experimental philosophy at Oxford from 1810 until 1839, formed a valuable working collection of books on physics, mathematics and astronomy, of which he made great use during the last decade of his life, when, as Savilian professor of astronomy, he was engaged on his great "Works and Correspondence of Dr. Bradley", 1831, and the much quoted "Correspondence of Scientific Men of the Seventeenth Century", published posthumously in 1841.

Rigaud's library is not only of unique value for the history of a third of the nineteenth century and of the first Radcliffe Observers, but it also includes earlier works as well. That this collection, even at considerable cost, should be kept together in its entirety for the benefit of future students, is the view of Exeter College of which Rigaud was a fellow, and was the view of those Radcliffe Trustees who purchased the collection for historical purposes about the time when the Duke of Marlborough, Sir W. Heathcote, Mr. W. E. Gladstone and Mr. Peel, Speaker of the House of Commons, were managers of that trust for charitable purposes. Also, but a few months back, it was the view taken by the late trustees, Lord Chelmsford and Lord Grey of Fallodon.

The solicitor now writes that the present trustees are contemplating a sale by auction. They have, it is true, given a first choice of books to the Bodleian Library and a selection of pamphlets to the Lewis Evans Collection. But the elimination of the remainder will seriously detract from the scientific value of these portions.

Such a dispersal is believed not to have been their original intention. Before the death of Prof. H. H. Turner it was, I believe, arranged that the entire collection would go to the Savilian professor; and quite recently an offer of the un-donated part of the collection, including many appropriate books on instruments, was made to the Lewis Evans Collection on the condition that the Bodleian should agree to place its recently acquired Rigaud books so as to restore the integrity of the whole library. This, however, the Bodleian found impracticable.

There is now a need for these books in Oxford as never before. The gift of the instruments of the Radcliffe Observatory to the new Museum for the History of Science is only half a gift, if the instruments are unaccompanied by the books of those who used them. The collection of Rigaud pamphlets in the Lewis Evans Collection cannot be adequately dealt with, without contemporary books of reference of their collector. The need of books of historical interest is urgent.

Soon after 1860, when the University Museum of Science was first founded, the Trustees transferred their general library there, to the great and lasting benefit of the University. Now that the University has founded a Museum of the History of Science for ordinary study and historic research, will not the Radcliffe Trustees reaffirm their original policy by adding books to the instruments, pamphlets and manuscripts of Hornsby and Rigaud with which they have endowed the new institution?

Even at this eleventh hour it cannot be too late for the Trustees thus to signalise the worth of their own Observers, and by conserving the whole of the Rigaud library, to earn the gratitude of future historians by giving instead of depriving them of the opportunity of doing for Hornsby, Rigaud and others, what Rigaud with his private library did for Hariot, Bradley and Newton.

The Concept of Time in Physics

IT would be in the highest degree ungrateful for me to cavil at Prof. Dingle's review of "The Serial Universe" in NATURE of February 9, and I have no intention of so doing. But his criticism of the immortality discussion—a criticism which has been made also by Prof. Stocks and Prof. Joad—arouses in me an uneasy feeling that the book has failed here to emphasise properly the salient points of the argument.

In all questions of continuity, the onus falls, of course, upon the contestant who asserts a boundary. The prisoner is presumed innocent until he has been proved guilty. That, indeed, is the only hope of observer 1, who is in the dock—on the circumstantial evidence of psychoneural parallelism—and is pleading for the benefit of any vestige of doubt that may remain. But observer 2 is in a superior position. He is not even accused. He stands beyond the range of the old indictment.

The comment which has been made now is that observer 2, though unaffected by the death of observer 1, may, later on in his own time, encounter some death of a higher-order description. But here the law of the regress must hold. Observer 3, in his turn, would be unaffected by the death of observer 2. Thus, the receding ultimate observer must elude

always any kind of death that science will permit us to bring into the picture.

The only escape from this would be to prove that there is a death 2 which, necessarily, *accompanies* death 1—to prove that the observer must die when his instrument breaks That is what I have sought for throughout the last nine years, and cannot find Apparently, such simultaneous (in absolute time) destruction of all the infinite series of observers would demand a miracle

Similar considerations apply in the question of free-will We may construct, at any stage of the regress, a picture which will include both subject and object ; and, in that picture, determinism will reign supreme But the ultimate observer (who is, incidentally, the draughtsman) remains outside the world thus pictured, and with power to intervene Prof. Stocks urges that this is merely an infinite series of evasions of the question. Yet, surely, it is clear that what is evaded is not the question, but the determinist verdict The ultimate observer is not the slave of any constraint that his science can picture

When no death can overtake you, and no objective circumstance can compel your choice. that is immortality, and that is free-will But the really interesting thing is that, when those intuitive claims of our consciousness are recognised in that serial fashion which is the essential foundation ('nominalist' or otherwise) of the time picture, then -and not until then—does the world of physics become rational

Feb 15

I THOUGHT Mr. Dunne's demonstration that time as it is used in physics, is a mathematical device which is justified because, and to the extent that, it is adapted to the interpretation of experience, one of the most valuable parts of his book It seems to me inadmissible to deduce qualities of experience from the character of a device voluntarily adopted to interpret it Experience is not at the command of the arbitrary machinery of logic

This seems to me almost axiomatic, but it might not be superfluous to go from the general to this particular case. If time is regarded merely as an indefinitely extended continuum—as in much physical work it is—it is not suitable for the complete correlation of our experience, because the fact that we necessarily move along it in a single direction is omitted We must therefore supplement this conception (T_1) by the addition of such a movement, thereby introducing T_2. T_2 thus earns recognition only because it repairs the inadequacies of T_1 As Mr. Dunne admirably shows (pp. 35–36), it was not inherently necessary to start with an inadequate conception. We can describe a fraction as 1/3 or as $0\cdot\dot{3}$, but if we adopt the second form it is necessary to continue beyond the first decimal place ; and, in the matter of time, field physics has not done so. But to jump from that to the *independent* significance, of T_2, in which the observing experiencing individual may survive after he has ceased to be in T_1, is logically impossible. One-third is insufficiently represented by 0·3, but it is still worse to call it 0·03.

If one has to say 'yes' or 'no' to the survival question, I agree with Mr Dunne that the onus of proof is on those who say 'no', but in science, unlike English law, 'Not Proven' is a possible, and often the only possible, verdict. I think it is so here.

Spectrum of Nova Herculis, 1934

THE emergence of a displaced *B* type absorption spectrum at the end of February, coupled with a drop in brightness to $3{\cdot}5^m$–$4{\cdot}0^m$, suggests that, after a most unusual life-history of two months, the nova is now developing along more normal lines Accompanying the O II and N II absorption lines—displaced with a velocity of about − 900 km/sec—there is to be seen an undisplaced bright band of [N II] at 5755·56 This can be traced back on the spectrograms to January 22.

We should like to correct our previous statement[1] that the forbidden lines of O I at 5577, 6300, 6363 A had not previously been found in novæ Dr W. H Wright observed the lines in Nova Ophiuchi, 1919[2], but the lines could not then be identified as [O I] It is of interest to note that, while in the aurora and the night sky spectra, 5577 is the strongest line and in the nebulæ it is too weak to be observed, it is found in the nova of varying strength, but frequently about the same strength as 6363

A Blue Flame in the System N_2O_5/O_3

WHEN dry nitric anhydride is vaporised in a stream of ozonised oxygen, and then passed through a glass tube heated by a small flame, the colourless gas becomes brown, through the formation of nitrogen dioxide, a short distance before the flame is reached A narrow zone of a dark grey-blue colour is, however, seen hovering at the boundary, and this is preceded by a zone of clear blue In a long tube, the blue flame thus formed 'strikes back' from time to time, at the rate of about 10 cm per second, to the point at which the gas enters the tube, which is then filled from end to end with brown nitrogen dioxide. When the concentration of nitrogen pentoxide is low, the grey boundary between the colourless incoming gas and its pale brown decomposition products remains stationary and does not strike back

It is suggested that the formation and disappearance of the blue zone may be due to the production and decomposition of a higher oxide of nitrogen ; for example,

$$N_2O_5 + O_3 = 2\,NO_3(\text{blue}) + O_2;\; 2NO_3 = 2NO_2 + O_2$$

The temperature at the boundary is probably below 100°.

Isomeric Forms of Complex Acetic Acid

THE synthesis of 1-carboxy-3-methyl*cyclo*hexane-1-acetic acid by Higson and Thorpe's method[1] gave rise to a small amount of the acid, m p 163°, originally obtained by oxidation of α-keto-3-methyl*cyclo*hexane-1 : 1-diacetic acid[2], accompanied by a low melting point gum which was ultimately resolved into a mixture of two crystalline isomers of this The application of Lapworth and McRea's synthesis[3], on the other hand, gave a more satisfactory yield of the acid melting at 163°, accompanied by only small amounts of the other isomers The isolation of three forms of the acid,

$$CH_2\left\langle\begin{matrix} CH_2 - CH_2 \\ CHMe - CH_2 \end{matrix}\right\rangle C \left\langle\begin{matrix} CO_2H \\ CH_2\,CO_2H \end{matrix}\right. ,$$

is explicable only on the basis of the assumption of a strainless form of the methyl*cyclo*hexane ring, and the corresponding acids obtainable from 3 3 dimethyl*cyclo*hexanone are therefore being investigated in this laboratory A full report will be published elsewhere in due course

Effects Produced on Rats by Synthetic Androsteron (Male Sex Hormone)

AT the request of Prof Ruzicka, I undertook the experimental investigation on male and female rats of the biological properties of androsteron and some of his other allied synthetic preparations The following are the first results with androsteron

(1) Androsteron contains both one rat unit of "Comb growth activity" and one rat unit of "whole male sexual activity" (as defined by me[1]) in from 175 to 179 γ, the rat unit approximating to, if not being equal to, the capon unit (Butenandt and Tscherning[2] and Ruzicka and co-workers[3])

(2) The effect of androsteron in increasing the weight of the atrophied prostate of castrated rats is nearly directly proportional to the dose with doses of from 0 2 mgm to 0 9 mgm, after which dose the curve flattens

(3) The daily dose of 1 8 mgm of androsteron injected into castrated rats for 21 days caused an increase in weight of the atrophied prostate by about 800 per cent and of the seminal vesicles by about 500 per cent, of the penis by about 200 per cent and of the preputial glands by about 180 per cent.

(4) In castrated males and in, ovariectomised females androsteron also caused the following changes : a return towards or to normal, a decrease in the weight of the adrenals (hypertrophied after castration), an increase in the weight of the liver, kidney and, in most males, to a slight extent the thyroid (which decreases after castration), the restoration of the normal rate of involution of the thymus, an increase in the appetite and gain in body weight Injections into castrated males also increased the weight of the heart (which is slightly decreased by castration)

In addition to these favourable results on the weight of the organs, histological investigation showed the absence of any toxic effect of androsteron in those organs of castrated rats the structure of which is not considerably changed by castration (liver, kidney and heart) and a return towards or to normal in those organs investigated the microscopical structure of which undergoes severe changes after castration (sexual organs, adrenals).

(5) Androsteron did not cause a return to normal (in weight or histologically) of the hypertrophied hypophysis of castrated males, nor did it produce œstrous in ovariectomised females even when injected in doses of 1·8 mgm for 21 days It also had no 'rejuvenating' effect on old male rats in the doses used (0 1 mgm and 0 9 mgm per day for 21 days)

Repetition of the assay with a second batch of androsteron and of some other experiments are in progress.

A Useful Indicator for the Passage of Food through the Alimentary Tract of Animals

THE following method has been used at this laboratory to indicate the distribution of bacteria in the alimentary tract of the rabbit at various times after they had been given *per os* It was found to work very satisfactorily and appears to have several advantages over the various colouring methods which have been used from time to time in observations on the passage of foods through the intestinal tract of domestic animals and birds.

The indicator is Lycopodium powder (used in pharmacy for covering pills) which is composed entirely of the spores of the staghorn moss, *Lycopodium clavatum* The powder requires to be placed in slightly soapy water before it can be wetted, but this is not necessary if it is to be mixed with food Lycopodium spores are easily recognisable under the microscope, but their chief merit as an indicator for the passage of food through the alimentary tract lies in the ease with which they can be recovered from the ingesta by means of the ordinary sugar floatation technique, as used for the recovery of nematode eggs from the fæces. It also has the advantage that a count of the spores can be made by any of the methods used for counting nematode eggs in fæces, and fairly accurate information so obtained post mortem on the relative amounts of the test dose in various parts of the alimentary tract

Oxygen Consumption of the Cockroach in Relation to Moulting

DURING experiments on the oxygen consumption of *Blatella germanica*, it was observed that one specimen which was used on the day of its last moult, when it was still pale in colour, had a respiratory rate about 50 per cent higher than the normal. Experiments were accordingly undertaken in which the rate of oxygen consumption of the last

stage nymphs of a related species (*Blatta orientalis*) was measured at intervals until after the animals had moulted and become adult. The Barcroft apparatus was used at 25° C.[1]

	Number of observations	Average oxygen consumption in mgm./gm./day, and standard error
11th to 2nd weeks before the moult	29	9·0±0·18
Day of moult and 3 days following	21	14·3±0·37
2nd to 4th weeks after the moult	26	10·4±0·20

Average live weight per animal = 325 mgm.

Ten animals were used, but in only four cases was it possible to carry out an experiment on the actual day of the moult. In these cases the average oxygen consumption was 16·5 mgm. per gram live weight per day, and the rate fell after that day. The accompanying table summarises the results obtained, the figures for the week before and the last four days of the week after the moult being omitted in order that the difference between the periods chosen may be clearly seen. The difference between the rates 'during' (that is, day of moult and three days after) and after the moult is more than nine times the standard error of that difference. The difference between the rates before and after the moult is also quite significant.

Little is known about the internal histological and metabolic changes which take place during the post-embryonic development of exopterygote insects, though they are not nearly so great as the changes accompanying metamorphosis in the Endopterygota[2]. The external skeleton is, however, partly digested and partly shed and a new cuticle is laid down in its place[3]. It is to this process of moulting alone, in the absence of further information, that we may ascribe at present the additional oxygen consumed at this period.

Collision Frequency and Molecular Density in the F_1 Layer of the Ionosphere

RECENT measurements of the reflection coefficient of the ionosphere, for radio waves between 60 m. and 100 m., have led to a method of determining the collision frequency of electrons and molecules in the region where the ionisation density of the F_1 layer is a maximum. This is, roughly, at a height of some 200 km. above the earth's surface.

The pulse technique of Breit and Tuve was used, and simultaneous records were made of the equivalent height and reflection coefficient of the ionised regions. At certain times the equivalent height rose rapidly to a great value and then decreased again. Simultaneously, the echo intensity decreased to a minimum and then increased again, the minimum intensity corresponding with the maximum equivalent height.

An example is shown in Fig. 1. Such results are interpreted on the supposition that, at the time of maximum equivalent height, the actual frequency ν of the emitted waves is very close to the maximum critical frequency ν_0 of the F_1 region. In such conditions, the extra attenuation shown by the dip in the curve (2) is caused by the collision of electrons with molecules which occur in the neighbourhood of the F_1 ionic density maximum.

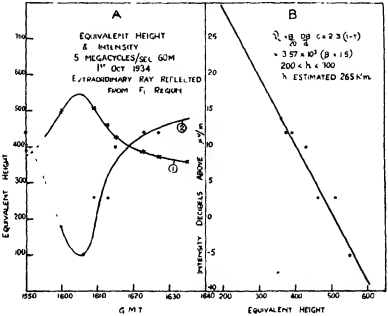

FIG. 1.

The reflection coefficient, in this case, can be shown to be $e^{-t/\beta\tau_c}$ for the ordinary ray, and $e^{-t/\beta\tau_c(1-\tau)}$ for the extraordinary ray, and this is true for vertical incidence whatever the direction of the terrestrial magnetic field. τ_c is the mean time between successive collisions of an electron with the molecules of the atmosphere, $\tau = eH/2\pi m\nu$, and β is a constant[1] equal to $\frac{3}{2}$.

Thus there should be a linear relation between the log intensity and equivalent height (proportional to the delay time t). This is illustrated in Fig. 1, *B*. The slope of this line will then give the collision frequency ν_c. In the example illustrated in Fig. 1, $\nu_c = 3·6 \times 10^3$ for an estimated height of 265 km.

The determination of ν_c involves no other quantities than the relative intensities and delay time t, which can be measured with a fair degree of accuracy.

Electric Impedance of Suspensions of Leucocytes

CONCENTRATED suspensions of rabbit white cells were prepared by the method described by Mudd, Lucké, McCutcheon and Strumia[1]. When obtained by this method, about 95 per cent of the cells are polymorphs. Microscopic examination and measurement of respiration showed that the cells were in a normal condition. The impedance measurements were made at 21·4° C. Suspensions having volume concentrations from 10 to 42 per cent, in buffered 0·95 per cent sodium chloride, were used and the resistivity R (ohm – cm.) and parallel capacity C (mμ F/cm.) were determined from 0·25 to 16,000 kilocycles per sec.[2,3] The values of R and C, as functions of the frequency, are shown for a 42 per cent suspension in Fig. 1.

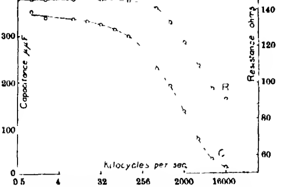

FIG. 1. Resistivity (R) and capacity (C) for a 42 per cent suspension of rabbit white cells (average diameter 10·5μ) in 0·95 per cent sodium chloride. Resistivity of intercellular fluid 69·0 ohms.

The theoretical method of treating these observations has already been described[2,3]. We distinguish between that part of the impedance of the white cell which is attributable to the surface and that part attributable to the interior. At low frequencies only the former part is effective and from the (approximate) constancy of C and R, at these frequencies, it is concluded that the impedance at the surface is due to the presence of a poorly conducting membrane which acts as a static condenser. By the same criteria, the presence of such a membrane at the surface of the erythrocyte and of the yeast cell has previously been established[2,3,4]. The capacity per sq. cm. of surface of the white cell can be calculated to be 1·0±0·1μF/cm.[2] This value is the same as found for the surface membrane of the erythrocyte[2], within the limits of experimental error. With the rather arbitrary value of 3 for the dielectric constant of the membrane, this capacity corresponds to a thickness of 27×10^{-8} cm.

From experience with other cells[3,4], it is likely that C and R increase slightly at the lowest frequencies. The theoretical significance of this increase as related to the ionic permeability of the membrane has been discussed[3,4]. Unfortunately, due to the rapid settling of the white cells, this increase cannot be accurately measured here, but it cannot be greatly different from that found for the red corpuscle. The decrease in C and R at about 128 kilocycles marks the point at which the interior of the cell makes its influence felt. The theoretical treatment is not sufficiently developed to allow us to recognise definitely any effects due to a polarisability of the membranes of the internal structures (nucleus, granules, etc.) but, within the present theoretical limitations, the impedance of the interior may be represented as a pure resistance, the specific value of which is calculated[2] to be 140±10 ohm – cm (21·4° C.). This value is, within experimental error, the same as found for the mammalian red corpuscle[5]. Since the organic matter content is nearly the same for these two types of cell, this agreement further strengthens the view that the impedance of the membrane of the internal structures in the white cell is negligible at the high frequencies for which the impedance of the internal fluid can accurately be determined.

Moving Striations

WE have recently completed an investigation of the spectra of moving striations in the positive column of some glow discharges. Briefly, the method consists in forming an image of the positive column along the slit of a spectrograph, and covering and uncovering the latter by a mechanical shutter made synchronous with the moving striations by a photo-electric device. This arrangement gives spectra, the individual lines of which show a longitudinal variation of intensity corresponding to the bright and dark sections of the striations.

In the case of a discharge in pure argon, we have examined the dark period carefully for high series lines or series continua, and find them absent. It would therefore appear that recombination of ions and electrons in the gas phase is not important, and since it is known from work by Kenty[1] on argon that such recombination is only appreciable when the average electron energies fall below about 0·5 e.v., we conclude that the electron energies in the dark periods exceed this amount. This is confirmed by the measurements of Pupp[2] who, in a recent paper, has described the results of probe analysis of somewhat similar discharges and finds in the dark phase electron energies in excess of 1 e.v. Our optical results are also in accord with his electrical data in that we have found that when a trace of mercury is present, the mercury arc lines 5461 A. and 4358 A. (excitation potential 7·6 volts) persist strongly through the dark phase although argon lines (excitation potential greater than 12 volts) are, at best, extremely feeble there.

It is satisfactory to find that the optical and electrical studies of these still puzzling phenomena are mutually confirmatory to this extent.

Accuracy of the Curie-Chéneveau Magnetic Balance

I HAVE read with interest, in NATURE of January 26, the letter by Messrs Gray and Cruickshank concerning the Curie-Chéneveau magnetic balance I may mention that I published a small work on this subject so long ago as 1914[1] I found that measurements within one per cent could be made with the greatest ease, and that it was possible to increase the accuracy, with some care, up to a precision of some tenths of one per cent at least The principal cause of errors and fluctuations were due to certain hysteresis effects in the moving parts of the apparatus (though non magnetic) and especially in the damping device My work was done with a somewhat improved type of apparatus due to P Weiss and A Piccard (unpublished, so far as I know)

F WOLFERS

Laboratoire de Physique Générale,
Faculté des Sciences d'Alger

[1] F Wolfers, "Mesures Magnétochimiques" Mémoire pour le Diplôme d'Études supérieures, Faculté des Sciences de Paris, 1914

Points from Foregoing Letters

NEW experiments by Dr C D Ellis and Mr W J Henderson with radionitrogen (the first radioactive element prepared synthetically by M and Mme Joliot by the action of α particles on boron) show that its half-life period is 11 minutes and not 14 minutes, it is thus identical with the half-life period of the radionitrogen obtained from carbon bombarded with protons The difference previously believed to exist between the two types of radionitrogen has been adduced as proof of the existence of negatrons (negatively charged nuclei)

Mr R W Gray's suggestion that whales can descend to 2,500 fathoms or more without suffering from caisson disease is disputed by Dr F D Ommanney He remarks that observations upon the behaviour of whales struck by harpoons offer little indication of their normal habits, and that descent even to two hundred fathoms would involve compression of the lungs to 1/35 of their usual volume

When α-particles hit nuclei of the lighter elements, they do not scatter according to Rutherford's rule (effective for the heavier elements) Prof G Beck and Mr L H Horsley submit a diagram illustrating the electrical barrier surrounding the nucleus, with its various 'energy levels' which are thought to determine the character of the scattering effect, they also indicate the type of scattering that has been observed with various light elements (Be^9, $B^{10, 11}$, C^{12}, F^{19}, Al^{27}) They infer that atoms of helium or lithium of mass 5 are unlikely to exist

Dr E Gross and Mr M Vuks submit photographs of spectra of light scattered by crystals of benzene and naphthalene and by liquid benzene, supporting their previous interpretation of the 'wings' observed around the primary line of the spectra, as due in part to slow vibrations of the molecules and not to rotation They point out that the central part of the 'wings', the intensity of which increases on heating, is characteristic of the liquid state

The Wilson cloud chamber, in which condensed water vapour renders visible the tracks of electrified particles, has been one of the most useful instruments in studying subatomic phenomena Mr P Kipfer has constructed a small high-pressure Wilson chamber in which gases compressed up to 100 atmospheres can be used This should increase the probability of atomic collision and reduce the time necessary for observations and the expense of taking a large number of photographs

Mr J W Dunne has put forward the view that time is polydimensional; he considers a succession of 'time within time', and is led by those considerations to assume the existence of freewill and immortality Prof Dingle, while viewing favourably the physical aspects of the hypothesis of 'serial time', considers Mr Dunne's psychological interpretations not justified

Prof T M Lowry and Mr J T Lemon describe an experiment which suggests that a higher oxide of nitrogen (NO_3) is formed transiently when a mixture of nitrogen pentoxide and ozonised oxygen is heated

Synthetic male hormone is found by Dr V Korenchevsky to increase the weight of the atrophied prostate, seminal vesicles, etc, of castrated male rats and to influence the development of female rats from which the ovaries have been removed It does not rejuvenate the male rats or induce œstrus in female rats, as reported for some of the testicular extracts

According to Mr E L Taylor, the spores of the staghorn moss, commonly known as lycopodium powder form a useful indicator for the passage of food through the alimentary tract of animals

Mr D L Gunn has found that there is an increase of about 50 per cent in the rate of oxygen consumption of *Blatta orientalis*, the cockroach, just after its last moult There is a similar rise in respiratory rate at the beginning and the end of the pupal period in insects which develop their wings inside the body until the pupal stage (Endopterygota)

From the relative intensities and delay time of radio pulses reflected from the F_1 electrically conducting layer of the upper atmosphere (about 200 km high), Mr T L Eckersley calculates the collision frequency of electrons and molecules in that layer

The electrical resistance (impedance) to alternate currents, of concentrated suspension of white blood cells (from rabbits) has been determined by Dr Hugo Fricke and Mr Howard J Curtis From experimental results and from special theoretical considerations, they deduce that for low frequencies the resistance measured is that of the cell membrane, while at high frequencies the resistance measured is that of the internal fluid of the cells The thickness of the cell membrane appears to be about 27 A, assuming an arbitrary value of 3 for its dialectic constant

Messrs Sloane and Minnis have obtained instantaneous photographs of the spectra of the moving striations which are a familiar feature of many commercial gas-discharge illuminating tubes They find that the variations of the spectra through the bright and dark parts of the striations are in accord with what is known of the electrical properties of this form of discharge.

Ethnology of Mysore. The Baron von Eickstedt, who himself has recently visited Mysore, contributes an introductory chapter on the racial history of Mysore in relation to that of India to "The Mysore Tribes and Castes", vol. 1 (Bangalore: Government Press). Mysore, like India as a whole, presents a fundamental contrast of open landscape and preponderantly mountainous jungle districts. Here also there is the same racial parallel: in the open country, settlements of a people of a progressive type, who are fair in the north of India and dark in the south and in certain refuge areas; and in the jungle districts primitive peoples who are fair in the western areas and dark in the eastern. Thus in India as a whole there are three main groups, each subdivided into two:—(1) The racially primitive peoples of the jungle region, the Ancient-Indians or Weddid racial group, divided into the Gondid race, a dark-brown curly (wide) haired people with totemistic mattock-using culture; and the Malid type, a black brown curly (narrow) haired people with originally ancient culture. (2) The racially mixed group Black-Indians, or Melanids, divided into the black-brown progressive people in the most southern plains with strong foreign matriarchy, the southern Melanids; and a black-brown primitive people of the northern Deccan with strong foreign (totemistic and matriarchal) influence, the Kolid type. (3) The racial progressive people of the open regions, New Indians or Indid group, divided into a gracile brown people with enforced patriarchy—Gracilo-Indid race; and a coarser light brown people with possible original patriarchal herdmanship, the North Indid type. So in Mysore is found the best preserved and most primitive of the primitive inhabitants of India, the Malids, with the later Gondids intruding, pro-Aryan North Indid herdsmen in the remnant of the Todas and traces of North-Indids all over the State, mixing with the older and partly younger intruders foreign to India, Palæo-mongolids, 'West-Brachids' and orientaloid Mohammedans.

Yao Education. In a study of the Yao tribe of Nyasaland, by Father Benno Heckel (University of London Institute of Education: Studies and Reports, No. 4. Oxford University Press. Pp. 53. 2s. net) an account is given of the initiation of boys and girls. These ceremonies represent a real fountain of life and are the basis of continued tribal existence. Information is difficult to obtain, as the greatest secrecy about them is maintained, and any violation would entail death. Initiation of boys takes place at 14–17 years of age. Each candidate is assisted by a patron, an elder man, who acts as tutor or instructor, and there is a leader, the 'Tail-bearer', who carries a zebra tail as a mark of distinction. The period of the initiation course is prolonged to three or four months, during the whole of which the novices must live in the place of initiation and submit to a severe discipline. They bathe before sunrise and are thereafter kept hard at work for the whole day. Ineradicable habits and perfect knowledge are inculcated by songs, hymns, dances and games. The course does not consist of abstract instruction, but of a pleasing and concrete form of education up to the standard of knowledge and practice of adult life. Sanctions corresponding to duties are taught by practical demonstration; for example, if punishment is death by a lion, on a very dark night the roaring of a lion nearby will be heard and continue until the novices promise fidelity. They are taught standards of politeness, hospitality and friendship, the history of the tribe and its phratries, tribal laws, rules of marriage, the names of the plants and animals they are not allowed to eat, the duties of marriage and conjugal intercourse and the like. After a ceremonial return to the village, the novices are considered to be adult, and undertake men's duties.

Geographical Variation in Number of Teeth. The Cyprinid family of fishes includes some two hundred genera distributed in all parts of the world except South America, Australia and Madagascar. The rows of pharyngeal teeth are distributed among these genera in numbers which have a clear geographical significance (V. D. Vladykov, *Copeia*, 1934, p. 134). Thus genera with three rows of pharyngeal teeth do not occur in America and one row genera somewhat exceed in number two row genera. In Europe about 9 per cent of the genera have three rows, and two rows are dominant. At the other extreme, Africa has only two one-row species and 90 per cent have three rows, species been taken here for comparison since the genera are few (8). The accompanying table shows more clearly than description could show the relationships of the numbers.

Regions	Percentage Nos. of rows of pharyngeal teeth			Total No. of genera
	1	2	3	
North America	46·0	40·5	--	37
Europe	41·0	50·0	9·0	22
East Asia	23·0	23·0	49·0	57
India	8·0	12·0	68·0	25
Africa (species)	0·6	3·0	90·0	262 species

Systematics of the Penæids. Mr. Martin David Burkenroad discusses the littoral and sub-littoral penæids of the world, the present studies being mainly centred about American Penæinæ and Eusicyoninæ ("Littoral Penaeidae chiefly from the Bingham Oceanographic Collection, with a Revision of *Penaeopsis* and Description of two New Genera and Eleven new American Species" (*Bull. Bingham Oceanographic Coll.*, 4, Sept. 1934). In further work he proposes to continue this revision to complete a monographic account of the group. The tropical west coast of America is found to be extraordinarily rich in penæids, ten of the eleven new species described in the present paper coming from the Pacific, one belonging to a new genus; and much that is new and interesting is shown in the distribution of the various species. A systematic revision was evidently much needed and the present account is full of careful comparative work based on the examination of material from different sources, necessitating certain alterations in the existing classification. Special attention is given to the petasma, for which a generally applicable terminology is prepared, and the internal morphology, homologies and probable mode of operation of the thelycum in a number of the Penæinæ are described, including a discussion of certain methods of separation of the entrance and exit to the sperm receptacles; a series of excellent text figures of these structures is given.

Amœboid Cells in Invertebrates A useful summary of the different kinds of amœbocytes and allied cells in invertebrates has been prepared by Isabel Haughton (*J. Roy Micro Soc*, 54, Pt 4, Dec 1934) The blood cells of invertebrates show types of stages corresponding with those found in vertebrates, but in addition are others, such as the adipo spherical cells (spherical cells filled with fat globules and protein spheres) found free in the cœlomic fluid of Annelida or aggregated into a tissue in insects, which do not correspond with any cells found in vertebrates Amœboid movement is common in the leucocytes of invertebrates, but the property of thigmotaxis—the spreading of the corpuscles when they come into contact with a foreign body—which is irreversible, has often been mistaken for amœboid movement which is reversible, for the pseudopodia can be withdrawn The leucocytes often exhibit phagocytosis, and they play a large part in digestion and excretion, especially in the bivalve molluscs, in which they ingest food material, as they lie between the epithelial cells in the wall of the stomach, and transport it thence to the connective tissue where they digest the food Coagulation of blood is found among invertebrates only in some Crustacea, the formation of clots in other invertebrates is due to agglutination or clumping of the blood cells. In the examples studied, phagocytes are widely distributed throughout the body, especially in connexion with the digestive organs and in the connective tissue Lymph glands have been demonstrated only in very few invertebrates and therefore the origin of the amœbocytes and blood cells is obscure Mitosis has been observed in the small hyaline cells, and the general impression is that from this the other types are developed by acquisition of granules

Development of a Braconid Parasite. Mr P M Glover, of the Indian Lac Research Institute, Ranchi, India, has recently published a paper on the development of *Bracon tachardiæ*, Cam (*Bull Entomol Res*, December 1934) The species in question is an ecto-parasite of the larva of the moth *Eublemma amabilis*, which is an important predator on the lac insect The first five larval instars of *Bracon* are described and certain structures are figured in some detail, while an analysis of their growth phases is given It is found that head-width is a safe indication of a given instar since extremes rarely occur, the widths calculated on Dyar's principle also approximate sufficiently closely to the observed widths to preclude the overlooking of an ecdysis The length of the mandible is identical in a given instar and its exuviæ, and allows of their grouping, particularly if averages be taken · the range for a given instar is wide, but the extremes do not overlap The factors for increase of head-width and mandible-length are fairly similar, falling near to 1·26 The growth of the body of the larva from instar to instar is independent of head growth, larvæ increasing in weight and volume by a figure lying between 3 and 4 times, from instar to instar, and closely approaches the theoretical figure for volume (3·6) It is suggested that similar observations may be true for other ectoparasitic Braconidæ

Bihar Earthquake of 1934. At the meeting of the Geological Society of London on February 6, a lecture on the Bihar-Nepal earthquake of January 15, 1934, was given by Dr. J A. Dunn, who directed the study of the earthquake on behalf of the Geological Survey of India The fracturing that caused the earthquake lay beneath the deep alluvium of the Gangetic plains The direction of oscillation was usually parallel to the trend of the epicentral region, not radial to it, suggesting that the initial movement was principally along the strike of the fault The total duration of the earthquake was about five minutes, most of the damage being done during the latter half of the disturbance Surface undulations, 6 12 ft long and perhaps 6 in high, were seen even at a distance of 200 miles from the epicentral area An interesting feature of the map of isoseismal lines is the occurrence of alternating zones of less and greater intensity outwards from the central tract, due probably to displacements along secondary lines of weakness Within the central isoseismals lay a belt, 190 miles long, in which tilting of buildings and collapse with subsidence of the ground was more marked than actual destruction by vibration The belt probably lay over that part of the fracture along which differential movement was greatest

Soil Survey in Berkshire The University of Reading has already published a soil survey of the county of Berkshire, but it was clear that an intensive study of certain areas with the use of more modern methods was desirable if an explanation was to be obtained as to why fruit growing had been able to establish itself as an important industry in a certain part of the Vale of the White Horse A detailed survey of this area has, therefore, been recently carried out by Dr F F Kay and the results published by the University of Reading as Bulletin 48, "A Soil Survey of the Eastern Portion of the Vale of the White Horse" The district was found to fall into four natural areas, which are described in detail, and the soils, classified on the basis of their soil profile characteristics, grouped into twenty soil series, the appropriate weed flora being described for each The calcareous nature of the majority of the soils necessitated the use of certain modifications of the usual methods of analysis especially in connexion with mechanical analyses and the determination of exchangeable potassium High figures for potassium saturation were correlated with a siliceous type of clay and free drainage conditions, and a classification of base saturated calcareous soils is suggested on the basis of the nature of the clay fraction The most useful fruit soils were characterised by free drainage conditions, a high degree of potassium saturation and a siliceous type of clay Excellent cherries could be produced on the Blewbury and Harwell series and very good quality apples grown on the Hendred and Harwell series Potash manuring was shown to be essential on the light loams of the Corallian

Dust in the Air. The January issue of the *Review of Scientific Instruments* contains a description of an instrument for taking direct photographs of dust in the air, devised by Messrs L H Ott and J B Ficklen, of the Sloan Physics Laboratory of Yale The usual methods of collecting the dust in water or allowing it to settle on a plate of glass, or making the air containing it impinge on a glass surface to which the dust adheres, they consider unsatisfactory, and have found that by using strong illumination they can photograph the dust particles. The air to be tested is drawn into the lower portion of a vertical tube which is then closed. The upper part contains a camera directed downwards and focused on a thin horizontal band of the air, which can be strongly

illuminated for an instant through a window in the side of the tube by a photographic flash lamp outside the tube. A supersensitive panchromatic film is used and the whole apparatus weighs only 5 lb. A photograph of chalk dust particles which vary in size from 1×10^{-3} to 5×10^{-2} cm is reproduced

Theory of the Auger Effect E H S Burhop (*Proc Roy Soc*, A, Feb 1) has investigated theoretically the radiationless transformation by which an atom ionised in, say, the *K* shell, may re-arrange itself by an electron falling in from another shell and giving up its excess energy to another electron, which is expelled from the atom The quantum mechanical approach is similar to that used by Hulme to consider the internal conversion of γ-rays Hydrogen-like wave functions were used to represent the two electrons, the nucleus being supposed to be screened according to Slater's rules The probability of transition between the initial state and the final state (one electron in the *K* shell and one electron unquantised) is calculated by means of a formula of Dirac, an allowance being made for the fact that either of two electrons may fall into the *K* shell, the other being ejected There is no means of distinguishing these processes experimentally The intensity of the *K* radiation is also calculated so that the probability of radiative and radiationless transformation may be compared Numerical calculations are carried out and compared with experimental results. The variation of the internal conversion with atomic number is satisfactorily given, and the variation of intensity among different transitions in the atom is also obtained in agreement with experiment

Transmutation of Sodium by Deutons E O Lawrence (*Phys Rev*, Jan 1) has made an extensive study of the nuclear reactions produced in sodium by H^{2+} ions having energies of 1 7 million volts The following transmutations take place

The production of radio-sodium

$${}_{11}Na^{23} + {}_{1}D^{2} \rightarrow {}_{11}Na^{24} + {}_{1}H^{1},$$

followed by

$${}_{11}Na^{24} \rightarrow {}_{12}Mg^{24} + e,$$

alternatively

$${}_{11}Na^{23} + {}_{1}D^{2} \rightarrow {}_{12}Mg^{24} + {}_{0}n^{1},$$

and possibly

$${}_{11}Na^{23} + {}_{1}D^{2} \rightarrow {}_{10}Ne^{21} + {}_{2}He^{4}$$

The radio-sodium was produced in considerable quantity (equivalent to about ½ mgm radium) and it is suggested that it may be produced in this way for biological work Its decay period was measured with an electroscope, and gave a value of 15 5 hours, similar to that of the radio-sodium obtained by Fermi by a different process Absorption measurements were made on the β rays, giving a probable maximum energy of about 1 2 mv About one γ-ray was found to accompany each β-transformation, the γ-rays being probably monochromatic and of energy of the order of 5½ mv These γ-rays should be valuable, for example, in the study of electron-positron pair production. The protons accompanying the activation of sodium were identified and their energy distribution studied The Gamow theory was found to account for the variation of radio-sodium yield with bombarding potential Neutrons and α-particles corresponding to the alternative reactions above were also found.

NO_3F. By the action of fluorine on moderately concentrated nitric acid, an explosive colourless gas of the formula NO_3F is produced (G H Cady, *J Amer Chem Soc*, 56, 2635, 1934) The vapour density is about 82, the boiling point about − 42°. The gas is fairly stable at room temperature, but explodes on heating It has an irritating odour. NO_3F is moderately soluble in water, with which it reacts slowly, liberating oxygen It liberates iodine from potassium iodide, forming a nitrate and fluoride, and reacts with potassium hydroxide according to the equation $NO_3F + 2OH' = \frac{1}{2}O_2 + F' + NO_3' + H_2O$

Mechanism of the Biological Oxidation of Ammonia. Messrs Gopala Rao and K M Pandalai, writing from the chemical laboratories of the Andhra University, Waltair, India, state that they have investigated the possibility of the formation of hydroxylamine as an intermediate product in the oxidation of ammonia by nitrifying bacteria Various tests for hydroxylamine were employed, but always with negative results There was no difficulty in detecting its presence after addition of small quantities to the cultures The positive results recorded by Mumford (1914) are attributed to the use of impure cultures, and the confirmation given by Mazé (1921), Kluyver and Donker (1926) and Fowler (1934) is not based on experimental evidence

A New Cold-Cathode Amplifying Valve. A paper entitled "An Electron Multiplier" describing a new type of cold-cathode amplifying valve developed by P T Farnsworth of the Television Laboratories, Ltd, U S A, has recently been received (*Electronics*, August 1934) This new valve is a high vacuum amplifier, which promises to find considerable application in television and other aspects of radio communication The valve is cylindrical in shape and contains two cold cathodes, one at each end, with a metal ring anode mounted centrally between them An electron produced photo electrically is accelerated towards the anode, which is maintained at a high positive potential relative to the cathodes A longitudinal magnetic field, produced by an external circuit, deflects the electrons, so that they miss the anode and strike the second cathode, where they produce secondary emission The additional electrons so produced then travel in the reverse direction and the whole process is repeated In order to ensure that the electrons arrive at the cathodes with sufficient velocity to dislodge further electrons, a potential difference of the order 25–90 volts at a frequency of 50 megacycles per second is applied between the two cathodes from a circuit tuned to this frequency As the secondary emission process builds up, the current in this tuned circuit increases; and this current can be controlled by the external magnetic field and by the steady voltage applied to the anode. A maximum effect is obtained when this steady voltage is such that the transit time of the electrons between the cathodes is an odd multiple of half the period of the oscillations. It is stated that the actual current magnification obtained is enormous, since the electrons may make as many as a hundred complete transits of the tube, each time producing as many as six secondary electrons per original carrier. Different types of valves have been produced for amplification and oscillation, but much further research appears to be needed on the problem of making the valves uniform and efficient.

Foundation of the National Institute of Sciences of India

AT the twenty-first session of the Indian Science Congress, held at Bombay in the first week of January 1934, the General Committee considered the various suggestions regarding the foundation of an Indian Academy of Sciences that had been made during the previous year, and appointed a representative committee with the object of drafting a constitution to be laid before the next meeting of the Indian Science Congress, and to take necessary steps to bring the Academy into existence

The General Committee was of opinion (Resolution II) that the principal purposes for which an Indian Academy of Sciences was desirable were

(i) To act as a co-ordinating body between scientific societies in India, institutions, and Government scientific departments and services

(ii) To act as a body of scientific workers of eminence to promote and safeguard the interests of men of science in India and also to act as a National Research Council

(iii) To publish a *comptes rendus* of papers read before the Academy and also Memoirs and Transactions

(iv) To promote and maintain a liaison between men of science and men of letters

(v) To secure and manage funds and endowments for scientific research

(vi) To do such other things as may be necessary for the promotion of science in India

This Committee had an original membership of 24, which was increased during the year to 39 by co-opting members representing various interests, as was found desirable The Committee held seven meetings and an emergency meeting At these meetings the various points of view were considered very carefully and a scheme for the foundation of a National Institute of Sciences of India was evolved

In accordance with the direction to take necessary steps to bring the Academy into existence, the Academy Committee had submitted its proposals to a hundred of the leading men of science of India representing all branches of science, and invited them to become its foundation fellows. An additional 25 scientific workers were invited to become foundation fellows on the vote of the first 100 foundation fellows, making a total of 125 foundation fellows The scheme makes provision for the election of not more than ten ordinary fellows annually, in addition to a certain number of honorary fellows

This scheme was placed before the General Committee of the Indian Science Congress held on January 3, 1935, and adopted unanimously, together with a recommendation that twenty-five ordinary fellows be elected in the first year instead of ten The proposal for adoption was moved by Dr L L Fermor on behalf of the Academy Committee and was supported by representatives of the General Committee (Prof P N Ghosh), Asiatic Society of Bengal (Sir U N Brahmachari), U.P. Academy of Sciences (Prof K N Bahl) and Indian Academy of Sciences (Prof B. Venkatesachar).

At the inaugural meeting, which was held on January 7, 1935, Dr. J. H. Hutton, as president of the Indian Science Congress, requested His Excellency Sir John Anderson, Governor of Bengal, to inaugurate the National Institute of Sciences of India

In inaugurating the first session of the National Institute of Sciences of India, His Excellency Sir John Anderson referred to the various stages in the progressive organisation of modern science in India He said that the foundation of a society of varied and comprehensive character, such as the Asiatic Society of Bengal, was the first stage, followed three quarters of a century later by the foundation of universities and specialist scientific services The third stage was reached half a century later with the foundation of the Indian Science Congress holding annual meetings of individual scientific workers, leading, after the lapse of a quarter of a century, to the foundation of a central and all-India co ordinating body, the National Institute of Sciences of India, embracing all modern scientific research in India

His Excellency's speech was followed by the presidential address of Dr L L Fermor, F R S, who has been elected its first president Dr Fermor traced the history of the development of scientific research in India in the twentieth century, leading up to the formation of the National Institute He further explained the co ordinating functions of the National Institute *vis-à-vis* the Academies of Sciences in India, and the method by which it is proposed to ensure their co operation The objects of the National Institute are stated to be "the promotion of natural knowledge in India including its practical application to problems of national welfare", which is indeed a very comprehensive programme

The Institute will act as a body of men of science of eminence to promote and safeguard the interests of scientific workers of India By the publication of a *comptes rendus* containing summaries of the papers read before all Academies of Science in India and by the preparation of an annual report on the progress of science in India in all its branches, it will focus attention on the research work being done in the country and indicate the lines in which progress is desired

The National Institute will also be prepared to act through properly constituted National Committees in which other learned academies and societies will be associated, and as the National Research Council of India, for undertaking such scientific work of national and international importance as required by the public and by Government. The National Institute and the Academies of Science in India will have mutually complementary functions and will co-operate with each other as independent organisations The National Institute will thus occupy a very important place in the scientific life of India, and its activities will be a potent factor in India's national progress

The inaugural meeting was followed by the first ordinary general meeting of the National Institute, which was held on January 8, 1935, in the rooms of the Asiatic Society of Bengal This meeting was attended by thirty-seven foundation fellows and a large number of visitors from among the members of the Indian Science Congress The result of the ballot for the election of the first council of the National Institute was announced at this meeting The Council for 1935 is constituted as follows.

President: Dr L L Fermor, director of the Geological Survey of India, Indian Museum, Calcutta

Vice-Presidents: Brigadier H J Couchman, Surveyor-General of India, Calcutta; Prof. B Sahni, professor of botany, University of Lucknow.

Treasurer · Dr S L Hora, assistant superintendent, Zoological Survey of India, Indian Museum, Calcutta

Foreign Secretary · Prof M N Saha, professor of physics, University of Allahabad

Secretaries Prof S P Agharkar, Ghose professor of botany, University of Calcutta Dr A M Heron, superintendent of the Geological Survey of India, Indian Museum, Calcutta

Members of Council Mr M Afzal Hussain, principal of the Punjab Agricultural College, Lyallpur, Punjab, Mr T P. Bhaskara Shastri, director of the Nizamiah Observatory, Begumpot, Hyderabad, Deccan, Dr S S Bhatnagar, university professor of chemistry and director of the University Chemical Laboratories, Lahore, Mr B C Burt, agricultural expert, Imperial Council of Agricultural Research, New Delhi (and Simla), Prof J C Ghosh, head of the Department of Chemistry, University of Dacca, Ramna, Dacca, Dr F H Gravely, superintendent of the Government Museum, Museum House, Egmore, Madras, Lieut Col R Knowles, professor of protozoology, School of Tropical Medicine, Calcutta; Dr K S Krishnan, Mahendralal Sircar professor of physics, Indian Association for the Cultivation of Science, 210 Bow Bazar Street, Calcutta, Prof S K Mitra, Khaira professor of physics, University of Calcutta, University College of Science, Calcutta, Prof J N Mukherjee, Khaira professor of chemistry, University of Calcutta, University College of Science, Calcutta, Dr C W B Normand, director-general of observatories, Meteorological Office, Poona 5, Prof Ganesh Prasad, Hardinge professor of higher mathematics, University of Calcutta, Dr Baini Prasad, director of the Zoological Survey of India, Indian Museum, Calcutta, Sir C V Raman, director of the Indian Institute of Science, Bangalore, Lieut-Col S S Sokhey, director of the Haffkine Institute, Parel, Bombay, Lieut-Col J Taylor, director of the Central Research Institute, Kasauli (Simla Hills), Mr S C Trevor, president of the Imperial Forest Research Institute, Dehra Dun, Mr F Ware, director of the Imperial Institute of Veterinary Research, Muktesar

The following representatives, in each case a vice-president and a member of council, of scientific bodies in India were also appointed

Asiatic Society of Bengal Sir U N Brahmachari, Medical College Hospital (Retired); Mr C C Calder, director of the Botanical Survey of India and superintendent of the Royal Botanic Gardens, Sibpur, Howrah

U P Academy of Sciences · Prof K N Bahl, professor of zoology, University of Lucknow; Prof. A C Banerji, professor of mathematics, University of Allahabad

Indian Academy of Sciences · Prof B K Singh, professor of chemistry, Ravenshaw College, Cuttack; Dr K V. A Krishnan, bacteriological research officer, School of Tropical Medicine, Calcutta.

Indian Science Congress Association · Dr J H Hutton, deputy commissioner, Naga Hills, Kohima, Assam, Mr W D West, assistant superintendent of the Geological Survey of India, Indian Museum, Calcutta

At this first ordinary meeting, eleven papers were read, the titles of which are given below

(i) "Synopsis of the Pre-Vindhyan Geology of Rajputana" by Dr A M Heron

(ii) "Physiology, Bionomics and Evolution of the Air-Breathing Fishes of India" by Dr S L Hora

(iii) "Problems of the Solar Corona" by Prof. M N Saha

(iv) "Ionospheric Height Measurements at Allahabad" by Mr. G R Toshniwal (communicated by Prof M N Saha)

(v) "On the Electron Theory of Metals" by Dr R C Majumdar, University of Lahore (communicated by Prof M N Saha)

(vi) "On Symmetrical Space with Minimum Rate of Expansion" by Prof N R Sen

(vii) "New Facts regarding Infection of *Citrus colletotrichum gleosporoides*" by Dr H Chaudhuri, Lahore

(viii) "Synthetic Enzyme" by Prof H K Sen and Mr Sobhanlal Banerji

(ix) "On the Question of the Expansibility of Zero in the Series of Legendre Functions having Non-integral Parameters" by Prof Ganesh Prasad

(x) "On the Cataphoretic Speed and Inorganic Colloids" by Prof J N Mukherjee, Mr S G Chaudhuri and Mr B N Ghosh

(xi) "Mon and Munda in India and Beyond" by Dr. J H Hutton

It may be confidently expected that the National Institute of Sciences of India will play an increasingly important part in the development of scientific research in India

Mechanical Testing of Timber

IN September 1928 a committee was appointed by the Committee of the Privy Council for Scientific and Industrial Research to report "On the Mechanical Testing of Timber" This report has now been issued (London H M. Stationery Office, 1934) The Committee had its origin as a consequence of work done during the War, in connexion mainly with the design of aircraft, when the testing of timber became a matter of particular importance; as was shown by the amazing development in aircraft construction and reliability In 1920, a report was published under the auspices of the Aeronautical Research Committee "On the Materials of Construction used in Aircraft and Aircraft Engines", by Lieut -Col. C. F Jenkin, professor of engineering science in the University of Oxford. Prof. Jenkin had served as director of the Materials Section of the Technical Department, dealing with the production of aircraft under the Ministry of Munitions Chap x of the report dealt with the mechanical properties of timber in a comprehensive manner

The Committee appointed in 1928 consisted of the late Sir Alfred Ewing (chairman), Prof. C F Jenkin, Prof. A Robertson and Messrs. W. D Douglas and C. J Chaplin The terms of reference were taken as implying "an unrestricted review of the testing of timber for strength and elasticity" This necessarily included consideration in detail of the methods of testing in use at the Forest Products Research Laboratory, Princes Risborough. Various investigations were carried out at this Laboratory during the course of the investigation. Other important experiments were carried out for the Committee by Prof E G Coker in his laboratory at University

College, London, and by Mr. Douglas at the Royal Aircraft Establishment.

The history of the development of the mechanical testing of timbers is not without interest. The system followed in most laboratories is practically that devised by the United States Forestry Service, and is the outcome of a scheme proposed in 1891 by Mr. B. S. Fernow, then chief of the U.S. Forest Service. At a somewhat earlier date, the Prussian Government had laid down a basis for timber testing, and Fernow stated that the two methods were practically the same, except that in the United States "the need of practically applicable results has been kept in the foreground". The American system received a further development about 1902 when it was adopted in the newly established Forest Products Laboratory at Madison, Wisconsin. In 1920, the U.S. Forest Service requested the American Society for Testing Materials to consider the standardising of timber tests, and the methods then formulated were adopted in 1925 by the newly instituted British Forest Products Research Laboratory. Before this, they had been substantially accepted in the procedure of the Forest Products Laboratories in Canada, India and New Zealand. They have also been adopted by Australia, the Federated Malay States and to some extent by Sweden, Poland and Japan.

The Committee points out that its investigations are only concerned with mechanical tests on small 'clear' specimens of timber—that is to say, specimens which are free from knots, shakes or other defects. The work of forest products laboratories, it realises, is concerned with both large and small specimens.

It is impossible here to follow the Committee through the investigation work carried out which enables it to form its conclusions. It should be mentioned that the testing methods in use at the time had been adopted as standard ones and included the British standard specification for methods of testing small clear specimens of timber (No. 373—1929) issued by the British Standards Institution. Although from a practical point of view the tests were the best that could have been devised with the knowledge then available, it was generally felt that several of the methods commonly employed were open to criticism from a scientific point of view. An opinion in this sense expressed to the Department in 1928 by Prof. C. F. Jenkin led to the appointment of the Committee which has presented the report now before us.

The Committee's Report concludes with the following: "Broadly speaking the several purposes for which mechanical tests for timber are, or may be, undertaken may be classified as follows:—

I. Tests which regard timber from the point of view of the physicist as a material for scientific examination, apart from any intended practical application.

II. Tests which regard timber from the point of view of the engineer as part of a structure that is to be designed to carry certain loads or perform other specified duties.

III. Tests appropriate for the grading of a number of timbers or for judging of their conformity to a given specification."

"Much, but by no means all, of the work of a Forest Products Laboratory falls within the third category and may properly involve methods of testing which would not be appropriate for the first purpose or even the second. On the other hand, tests suitable for the first purpose, or the second, are often attended by difficulties and restrictions which would put them out of court as matters of routine. It is clearly desirable that, subject to these considerations, the interpretation of all tests should be intelligible and their results definite, but it should be recognised that in providing for the various purposes here roughly indicated, tests of widely different character must be contemplated and they will be subject to different canons of criticism."

Timber testing has a growing value in the world of to-day, and the work of this Committee will be received with high approval and gratitude by research centres throughout the world.

National Inland Water Survey

THE paper on "National Inland Water Survey" by Dr. Brysson Cunningham, read at the meeting of the Royal Geographical Society on March 11, set out the scope of a survey required, not merely to serve the responsibilities of the Ministry of Health in regard to water supply for domestic purposes, but also to meet the needs of industry and commerce, the possible development of hydro-electric motive power, the requirements of irrigation, fisheries and navigation, the drainage of low-lying lands, the prevention of floods and other equally important matters. It defined a national survey, in the technical and only satisfactory sense of the word, as a comprehensive and accurate measurement and complete registration, so far as may be practicable, of all the water to be found in a country, whether contained in lakes, rivers, streams, wells, artificial reservoirs, or subterranean strata and cavities. A survey, it stated, should be regarded as a purely scientific undertaking, necessitating special technical knowledge and supervision, and in order to ensure its absolute impartiality, where so many different and possibly conflicting purposes are to be served, it should, as recommended by the Committee of the British Association, be conducted by an organisation "independent of any interest in the administration, control or use of water", such an organisation being available in the Department of Scientific and Industrial Research, which is equipped for work of this kind and possesses the essential scientific authority.

Proceeding to outline the programme of a survey, attention was directed, in connexion with rainfall, to the work of the British Rainfall Organization, which for a number of years past has carried out in an admirable manner the superintendence, collection and publication of data. Evaporation and soil absorption have not yet received the degree of attention needed for the purposes of a survey. It is also a regrettable fact that, up to the present time, there has been no department, or central organisation, constituted to deal with direct hydrological measurements of the amount of water actually derived from rainfall. While certain undertakings take gaugings for their own purposes, these are relatively few and the observations are not accessible by the public. The determination of run-off, that is, the bulk of the water which, following rainfall, escapes to the sea, constitutes therefore the greatest field of activity for

the survey The records of the Thames Conservancy at Teddington Weir were instanced as one of the few cases of really effective river measurement In England and Wales, much assistance in regard to stream gauging can be rendered by the Catchment Boards instituted under the Land Drainage Act, 1930.

The investigations of the British Association Committee were briefly described, and Dr Cunningham then proceeded to review the methods and organisations adopted in certain other countries, namely, Canada, the United States, France, Germany, Switzerland and Italy A number of lantern slides were exhibited illustrative of typical apparatus and installations in operation in the respective services It was shown that in all these countries, in addition to rainfall measurement, great importance is attached to the consistent gauging and measurement of river- and stream-flow and to the publication of the results obtained, so as to be accessible by all who are interested

Dr Cunningham urged that it should be considered an essential part of the duty of those in charge of a survey to disseminate information and advice to local authorities and others engaged in the exploitation of water supplies and the control of floods Finally, he said it would largely nullify the value of a survey if it were limited to the mere collection and filing of records and statistics The keynote of the organisation should be active research.

Fungi of South Australia

A VERY useful series of handbooks on the flora and fauna of South Australia is prepared by the British Science Guild (South Australia Branch) and published by the Government of South Australia The editorial committee shows that "there is an admitted lack of inexpensive but accurate books dealing with the plants and animals of South Australia, and it is felt that the absence of such has been a real handicap to young Australia, and so to the progress of Australian Science"

Handbooks on the general flora, mammals, fishes, the building of Australia and the succession of life, crustaceans, and reptiles and amphibians have already been published, while seaweeds, spiders, moths and butterflies, ants and birds are to be described in future volumes The gratuitous services of recognised authorities on particular subjects have been obtained, whilst the Government of South Australia publishes the volumes at low prices In spite of the serious depression through which South Australia has been passing, the Government has shown a commendable breadth of vision, and earned the gratitude of all scientific workers by continuing to publish this series

Part 1 of the handbook on "Toadstools and Mushrooms" before us is by Prof J. B Cleland, chairman of the Handbooks Committee, and combines scientific exactitude with a simplicity of statement which should bring the knowledge within reach of any intelligent person. The introductory sections are particularly well written. They deal first with general questions of distribution and activity, and then with uses of fungi, poisoning, fungi and art, localities affected by different species, fungi and bush fires, larger fungi eaten by mammals, insects and other animals, luminescence of fungi, fairy rings, mechanical force exerted by fruiting bodies, methods of collection and preservation, and descriptions of special terms used in classification

This takes up forty pages of closely-printed text, and the remaining 138 pages are devoted to a general classification of the higher fungi, and to a detailed classification of the Agaricaceæ The system adopted for the latter combines the orderly, reasoned groupings set forth by Carleton Rea (in "British Basidiomycetæ") with the convenient detail of Claussen's subdivision by spore colour This combination is used by the foremost students and teachers of mycology in Great Britain Convenient keys to the species, as well as to the genera, are given

Thirty-five photographs and drawings and six coloured plates enrich the text, and the price of five shillings is certainly extremely low for such a volume Copies may be obtained from the Government Printer, North Terrace, Adelaide British students of mycology can find a wealth of helpful description for many of our native species

University and Educational Intelligence

CAMBRIDGE —The Department of Scientific and Industrial Research has offered £2,300 for building and equipping an extension to the Low Temperature Research Station on its southern side It is to be used in perpetuity for scientific research and in the first instance for research on problems arising out of the preservation and handling of foodstuffs In the letter making this offer, it is stated that the Committee of Council has had under consideration the possibility of further extensions of the Station in the future, and that the only areas where such extensions appear to be practicable are at the southern end of the eastern side of the Station and at its north-eastern corner Having regard to the developments which have taken place since the Station was first erected, the Committee considers it desirable that these two areas should be reserved against future needs

The Smith's Prizes are awarded to H G Booker, of Christ's College, and L Howarth, of Gonville and Caius College Rayleigh Prizes are awarded to A F Devonshire, of Trinity Hall, T E Faulkner, of Gonville and Caius College, and F Smithies, of St John's College

EDINBURGH —The Senatus Academicus has resolved that the honorary degree of LL D be offered to the following, for conferment at the Graduation Ceremonial to be held on June 28 —The Right Hon. Lord Bledisloe of Lydney, Governor-General and Commander-in-Chief of New Zealand , Dr Nicholas Murray Butler, president of Columbia University, New York , Dr James L Garvin, editor of the *Observer* , Mrs M M Ogilvie Gordon, geologist, and vice-president of the International Council of Women , Prof J Graham Kerr, regius professor of zoology in the University of Glasgow , Prof John Laird, regius professor of moral philosophy in the University of Aberdeen ; Sir George Macdonald, formerly secretary of the Scottish Education Department, archæologist, numismatist and historian ; Mr. John Donald Pollock, Surgeon-Commander R N V R. medical service during the War ; Dr. A. N Richards, professor of pharmacology in the University of Pennsylvania ; The Hon Lord St Vigeans, formerly chairman of the Scottish Land Court

DR L FARKAS, who has been working in the Department of Colloidal Science in the University of Cambridge for the last two years, has been appointed lecturer in physical chemistry and head of the new Department of Physical Chemistry in the Hebrew University, Jerusalem, Palestine

THE University of Durham inaugurated in October 1924 a Department of Science, and a statistical summary of the work accomplished in it in the ensuing ten years 1924-34 has now been published Its educational work has been mainly for the benefit of prospective school teachers, these numbering 220 out of a total of 304 students who entered for undergraduate courses, but a substantial volume of original work has been done Excluding book reviews and other miscellaneous publications, original papers, including books, published from the Department between October 1924 and December 1934, numbered 118, of which a large proportion, 49, were concerned with geology, local or general A distribution of undergraduate students in 1934 among subjects assigns to physics 47, geology 39, mathematics 36, chemistry 34, botany 22 and geography 4

Science News a Century Ago

Improvements in Iron Manufacture

On March 16, 1835, Dr Clark read a paper "On the Application of the Hot Air Blast in the Manufacture of Cast Iron", to the Royal Society of Edinburgh. After giving a general account of the manufacture of cast iron, he said that the method first suggested by Mr Neilson of Glasgow and tried at the Clyde Iron Works consisted of previously heating the air thrown into the blast furnace. The method was found to produce a vast saving of fuel and of flux During the experiments made in 1830, the air was heated to 300° F In 1831, Mr Dixon of the Calder Iron Works thought of substituting raw coal for the coke which had hitherto been employed for fuel, at the same time heating the air to 600° F. The result was that three times as much iron was now made by the use of a given weight of coal as formerly

Geology of the Cordillera

On March 11, 1835, H M S *Beagle* anchored again at Valparaiso, and a few days later Darwin set out to cross the Andes to Mendoza by the Portillo Pass. In his account of the journey, he recorded on March 19, 1835: "All the main valleys in the Cordillera are characterised by having, on both sides, a fringe or terrace of shingle and sand, rudely stratified and generally of considerable thickness. . . No one fact in the geology of South America interested me more than these terraces of rudely-stratified shingle. They precisely resemble in composition the matter which the torrents in each valley would deposit, if they were checked in their course by any cause, such as entering a lake or arm of the sea; but the torrents, instead of depositing matter, are now steadily at work wearing away both the solid rock and these alluvial deposits, along the whole line of every main valley and side valley It is impossible here to give the reasons, but I am convinced that the shingle terraces were accumulated during the gradual elevation of the Cordillera, by the torrents delivering, at successive levels, their detritus on the beach heads of long narrow arms of the sea, first high up the valleys, then lower and lower down as the land slowly rose If this be so, and I cannot doubt it, the grand and broken chain of the Cordillera, instead of having been suddenly thrown up, as was till lately the universal, and still is the common opinion of geologists, has been slowly upheaved in mass, in the same gradual manner as the coasts of the Atlantic and Pacific have risen within the recent period A multitude of facts in the structure of the Cordillera on this view receive a simple explanation "

Investigations on Vesuvius

At the Royal Society on March 19, 1835, Daubeny read a paper entitled "Some account of the Eruption of Vesuvius, which occurred in the month of August 1834, extracted from the manuscript notes of the Cavaliere Monticelli, Foreign Associate of the Geological Society, and from other sources, together with a Statement of the Products of the Eruption, and of the Condition of the Volcano subsequently to it". After the eruption, the author had descended twice into the crater, which then presented a comparatively level surface, its sides consisting of strata of loose volcanic sand and rapilli, coated with incrustations of common salt, coloured red and yellow by peroxide of iron. The vapours which issued from the various parts of the surface, collected and condensed by means of an 'alembic' introduced into the ground, were found to consist principally of steam and muriatic acid, with only a slight trace of sulphurous or sulphuric acids The author considered that carbonic acid was also exhaled, but neither nitrogen nor sulphuretted hydrogen appeared to form any part of the gas emitted

The London and Greenwich Railway

In a note in its issue of March 21, 1835, the *Mechanics' Magazine*, referring to the London and Greenwich Railway, the first railway running out of London, said, "the Greenwich Railway will certainly not be ready to take passengers to the fair on Easter Monday, although according to some sanguine expectants, it was to be ready for that purpose two years ago It is still progressing, however, and some of its arches have now made their appearance at the London Bridge end of the line, close to Tooley-street It is understood that a locomotive will ply at Easter, for the conveyance of passengers on that part already completed, of course, such a trip will be taken more for the gratification of curiosity than for the sake of utility A plan has been broached for erecting a landing place for steamers at Deptford, in connexion with the railway The success of such a speculation, however, is problematical. In nearly the same time that it would take steam-vessel passengers to land at Deptford, and get seated 'all right' in the railway carriages, they might by going on in the steamer, be at the end of their voyage, and could the transference be effected with even instantaneous rapidity, the railway carriages could not land passengers in the city, as the steamers now do, but in Tooley-street, Southwark, a good quarter of a mile away" As originally planned, the railway had 878 arches, and alongside the line was to be a tree shaded road, a parade for invalids and children "incomparably superior to the boulevards of Paris".

Societies and Academies

LONDON

Royal Society, March 7 C T R WILSON and J G WILSON On the falling cloud-chamber and on a radial-expansion chamber The advantages of removing a cloud-chamber from a confined space such as that between the poles of a magnet by letting it fall, and photographing the tracks while the chamber is falling freely, are pointed out A new type of cloud-chamber, which has the form of a shallow cylinder with plane glass ends and in which the motion of the air during expansion is radial, gives good results It is found, as anticipated, that dropping the cloud-chamber and photographing while it is falling freely enables undistorted track pictures to be obtained (by eliminating gravity) when the interval between expansion and illumination is prolonged to such an extent, that with the cloud-chamber stationary, distortion by convection currents has become serious P I DEE and C W GILBERT The transmutation of heavy hydrogen investigated by the cloud track method The ${}_2He^3$ nuclei produced in the reaction

$$ {}_1H^2 + {}_1H^2 \rightarrow {}_2He^3 + {}_0n^1 $$

have been detected in the expansion chamber by passing a beam of artificially accelerated ${}_1H^2$ ions into a gas mixture containing heavy hydrogen The range of this group of particles has been measured and is $4\ 3 \pm 0\ 2$ mm for zero bombarding energy The neutrons produced in the same bombardment have an energy of $1\ 8 \pm 0\ 2 \times 10^6$ electron volts These results are in agreement with the application of the conservation of momentum to the process assumed A value of $1\ 0080 \pm 0\ 004$ is thereby deduced for the mass of the neutron

Royal Danish Academy of Science and Letters, November 2. NIELS BOHR On the applicability and limitation of the methods of classical physics in the description of collision and radiation processes

November 30 L. KOLDERUP ROSENVINGE: Distribution of the Rhodophyceæ in Danish waters Statistical investigations on the distribution of the Danish Rhodophyceæ show that the number of species decreases greatly from the northern Kattegat to Bornholm The species dominant in the south, which are, however, common in the northern districts, decrease more rapidly, with the consequence that the northern species are more numerous than the southern in the intermediate zones ØJVIND WINGE: Experimental alteration of sex chromosomes into autosomes and vice versa, as illustrated by *Lebistes*. The common view concerning the distribution of the sex-determining elements in the sex chromosomes and the autosomes is incorrect Female, as well as male, genes are present in the autosomes, and by systematic selection of male or female autosomal genes the sex may be changed In the experimentally produced *Lebistes* race in which both sexes have XX, 50 per cent of each sex are born in the spring, while nearly 100 per cent of females are born during autumn and winter, the external conditions having some influence upon sex determination in this race Besides normal XX females and XY males, the following types have been produced XX males, YY females, and YY males By crossing the XX males to normal females, all the offspring will be female, while YY males give only male offspring when crossed to normal females XY females crossed to normal XY males give males and females in the proportion 3 : 1, as expected The male-determining element in the Y chromosome is at one end. The gene contents of the sex chromosomes have been partly mapped out.

WASHINGTON, D C.

National Academy of Sciences (*Proc*, 20, 601–681, Dec 15, 1934). T E STERNE The accuracy of least squares solutions (2) The standard deviation of the errors of linear equations of condition MARGARET B SILER: Chromosome numbers in certain Ricciaceæ. Two basic numbers are found, 8 and 9, these include one chromosome very much smaller than the remainder HENRY E MERRIAM and JOHN E. RUTZLER, JR Reversible coagulation in living tissue (13). Caffeine increases the reflex excitability of the central nervous system from above downwards, and it causes insomnia It can be counteracted by an appropriate dose of sodium rhodanate G A. LEBEDEFF: Genetics of hermaphroditism in *Drosophila virilis* The third chromosome recessive gene (intersex) causes reversion of homozygous females to sterile males. Modifiers determine the time when this gene becomes active and hence the degree of hermaphroditism C. W METZ and E H GAY: Organisation of salivary gland chromosomes in *Sciara* in relation to genes These chromosomes shows 'bands' or 'discs' causing striations similar to those observed in the salivary gland cells of Diptera The strain of *Sciara* used shows regularly one particular 'vesicle' extending only half-way round the chromosome. Observation of fixed and living material suggests that, in the region of this 'vesicle', the two component chromosomes are not fused to form a cylinder, but lie side by side The 'vesicles' or 'segments' of different regions differ slightly and seem to be the 'chromioles' thought by Belling to represent genes W E CASTLE Body size of reciprocal hybrids in rabbit crosses If chromosomal genes alone function in the genetic determination of body size, then reciprocal crosses between pure races of different size should give identical results In such crosses between a large and three smaller races of rabbits, the offspring of large female mated with small male are, however, significantly larger than those of small female crossed with large male CHESTER STOCK A Hypertragulid from the Sespe Uppermost Eocene, California W W COBLENTZ and R STAIR Ultra violet transmission changes in glass as a function of the wave-length of the radiation stimulus Soda lime-silica and soda silica glasses show stages in photo-chemical equilibrium which are different for each wave-length of homogeneous radiation to which the glass reacts, and the soda seems to be the sensitive constituent To attain each stage of equilibrium, transmission may increase or decrease, according to the history of the specimen For wave-length 254 $m\mu$ and shorter, depth of penetration is small, for wave-length 365 $m\mu$ and longer, penetration is deep The shortest and the longest wave lengths used had the greatest photo chemical effects, namely, in depreciating and appreciating respectively the transmission of a soda lime-silica glass J L SYNGE On the expansion or contraction of a symmetrical cloud under the influence of gravity. A discussion employing invariant equations consequent on the usual field equations JOSEPH HALL BODINE. To what extent is developmental block dependent upon the metabolic activity of the embryonic cell? By immersing grasshopper eggs showing developmental block in hypertonic balanced salt solutions, it is shown that the block is not primarily dependent on the general oxidative metabolism and indeed that the oxygen consumption rate itself is a result of the block SELIG HECHT A theoretical basis for intensity discrimination in vision Photo-reception requires (*a*) an inactive photo sensitive substance which absorbs light and is changed by it into an active substance responsible for the nerve impulse, and (*b*) a mechanism for maintaining the supply of sensitive substance Equations are developed describing such a photo chemical system, and they give curves which fit the experimental results for *Drosophila*, the bee, the clam and the human eye Contrary to earlier results, it is found, in accordance with this theory, that $\Delta I/I$ (where I is intensity), after decreasing rapidly with increase of I, reaches a constant low value and does not rise again after passing through a minimum J S NICHOLAS and DOROTHEA RUDNICK The development of rat embryos in tissue culture The medium used was heparinised rat plasma plus rat embryonic extract Embryos of presomite to early 5–7 somite stages were observed up to 72 hours after explantation Growth and differentiation occur, but in 48 hours are one half and three quarters respectively of that of controls L H KLEINHOLZ Eye-stalk hormone and the movement of distal retinal pigment in *Palæmonetes*. Eye-stalks of this shrimp stimulated by light secrete a hormone causing inward migration of distal pigment cells; no substance of opposite action appears in the dark, so that the outward movement of the pigment cells appears to be inherent in the pigment cells themselves. Co-operation of State and Industry in Scientific Research*

ONE of the most valuable features of the annual report issued by the Department of Scientific and Industrial Research is what may be termed the map of research throughout Great Britain which it provides, in addition to the many impressive illustrations contained in the report of the way in which scientific research serves both industrial and social needs This map of research is of special interest at the present time Not only does the report indicate the direction which research upon urgent problems as housing and building, road transport, fuel supply and the like is taking, but it also indicates, as few if any other public documents do, the manner in which the resources of the State and of industry are being mobilised for the support of such research

From its inception, the work of the Department has been conditioned by the support it receives from industry Grants to the research associations have largely been on a pound for pound basis with contributions from the industry, and a good deal of work has been undertaken on specific problems for which appropriate fees have been paid by the industry or firm concerned The report of the Advisory Council for the year 1933 34 pays special attention to the various problems of co-operation presented in the work of the Department and to the methods by which effective and sustained research on fundamental and long-range problems is to be encouraged

Research work of this type is encouraged by the Department in several ways In the first place, there is a system of research grants to students, a scheme by which the Department is brought in direct contact with some of the fundamental scientific work at the universities A major advantage of this method is the assistance afforded to promising students to complete their training by a course of post-graduate study and research, and it is accordingly of considerable significance in regard to the recruitment of scientific staff by industry

In the second place, under the research association scheme various problems of fundamental importance are being investigated, and it is with the object of encouraging such long-range investigations that the Advisory Council is recommending, where circumstances warrant it, and conditional upon support from the industry,

* Department of Scientific and Industrial Research. Report for the Year 1933–34. (Cmd 4787) Pp iv+192. (London H.M Stationery Office, 1935) 3s. net.

substantial block grants for periods such as five years In this way, by stabilising the finances of the research associations, it is hoped to facilitate intelligent planning and prevent the crowding out of vitally important researches, which may not be immediately productive, by *ad hoc* inquiries

It is not, of course, suggested that even this scale of operations is one with which the industries should be content, and the Advisory Council has indicated its readiness to encourage further expansion by grants based on income in excess of a specified figure up to a prescribed limit There are, however, practical as well as financial limits to the expansion of the work of a research association, and in the majority of industries it will probably be found that, while the research work carried out by individual firms tends to increase, the activities of the research association tend to be limited to the more fundamental problems and to problems which are of interest to other industries also

The size of the average industrial unit naturally has some bearing on the future and final functions of a research association, but even when an industry maintains numerous research departments in its individual units and when the invaluable educational work of the research association has been achieved, there should remain a well-defined field of activity for the association, resembling in some respects the field of activity of a number of the research boards of the Department at the present time

Apart altogether from the suitability or necessity of the research association scheme for every industry, there is a third way in which the Department encourages scientific and industrial research —in actual financial co-operation with industry The co-operation we are now discussing is distinct from those special investigations or tests which individual firms or organisations ask the Department to carry out in its research stations and notably at the National Physical Laboratory, as a repayment service The current report refers to the extensive use made of the facilities of the stations of the Department by industrial undertakings in this way, but we are now referring to the encouraging growth in the volume of work undertaken by the Department as a demonstration to industry of the value of co-operation in the conduct of researches or investigations which are either too expensive or too lengthy to be attempted save by some large industrial association or by a group of firms

The cost of researches of this type is largely defrayed by contributions made by the co-operating firms, either directly or through some industrial organisation, and the balance of the cost is provided by public funds The expenditure, in contrast to that on a research association, is directed to specific researches, and in this way are handled many problems needing attention which could not be dealt with through a research association As an example of this type of co-operation the current report cites the researches at the National Physical Laboratory for the practical development of steels for use at high temperatures, financed as to at least one half from funds raised by the British Electrical and Allied Industries Research Association and the British Iron and Steel Federation Other examples are to be found in the work of the Steel Structures Research Committee, and the investigations to discover British sources of materials which could be used in place of natural pozzolanas to increase the resistance of concretes and mortars to certain forms of chemical attack

That there is a definite field for this type of co-operative research, even when the industries concerned are run on scientific lines and are conducting independent research on an extensive scale, is indicated by the support of the investigations last mentioned by such firms as Imperial Chemical Industries, Ltd , the Anglo-Persian Oil Co , Ltd and the Associated Portland Cement Manufacturers, Ltd The unconditional cash contributions made to the general work of the Department in special fields by industrial firms or associations may be regarded as another indication of the way in which the Department is regarded by progressive industry as supplying the essential staff work of research in fields which are important to many industries but the particular concern of none

It is, of course, difficult to disentangle work of this type, which finds a permanent place in our national structure of research, from more educational work, which will become less and less necessary as a scientific outlook is developed in all sections of industry and the support of research on an adequate scale becomes general The encouraging fact that the current report is able to quote three examples of researches which during the year have been transferred to the supervision of industry on the ground that their value to industry has now been fully demonstrated, while illustrating the success of the educational work of the Department, should not be taken as evidence that the need for co-operation between industry

and national research stations in this way will tend to disappear

There is a further aspect of the work of the Department which should not be overlooked Among the contributions received against the gross expenditure on the National Physical Laboratory, for example, are large sums from the Air Ministry and other Government departments As the report shows, the Department is responsible for a good deal of scientific work on problems put before it by various Departments of State.

The Advisory Council's report indicates, moreover, that the influence of the Department is not limited to securing industrial and departmental co-operation in research in Great Britain only In certain fields such as those of food investigation, both storage and transport, and timber research, it has from the start encouraged scientific co-operation with the Dominions overseas, and in many ways the resources of the Department are freely available for Dominion and Colonial Governments To this policy may be traced the considerable developments in research organisation in South Africa, Canada, Australia and India, and contributions amounting to nearly £10,000 which have been received from the Empire overseas indicate the way in which the value of this co-operation is appreciated Every effort is being made to secure scientific co-operation between workers at home and abroad so that ideas and results in parallel inquiries may be freely pooled

It is clear from this brief review of the essential functions of the Department that its work fills a definite and permanent place in our national research organisation The relative importance of the research associations and the research stations under the Department and of *ad hoc* investigations in co-operation with industry may vary as the work of encouraging a scientific outlook in industry and the prosecution of research on an adequate scale succeeds, but each has its own definite place in the national economy

What is equally clear from any survey of the activities of the Department is the uneven distribution of research through the industries of Great Britain While industries can be found where expenditure on research may approach in magnitude the whole budget of the Department, there are other industries the expenditure of which in this matter is grossly inadequate and out of all proportion with their expenditure on such matters as telephone or postage For many years yet, it is highly probable that by means of the research associations and in other ways the Department must continue its work of fostering the support of research by industry itself, both through the evidence afforded of the value of scientific research to industry in the past, in assisting the application of existing knowledge to industrial problems, and by encouraging the use of the scientific method in all branches of industrial activity

The fullest use cannot be made of the national structure of research, however adequate, unless a scientific outlook and the vigorous and continuous examination of manufacturing practice in the light of available technical knowledge are characteristic of industry everywhere The assertion of the Advisory Council in its report three years ago has lost not one whit of its force under the conditions obtaining to-day ' Scientific research has in the past made striking contributions to industrial progress and it will make them in the future But the nation which will enjoy the benefits of science in the day-to-day progress of its industries is the nation which habitually applies scientific method and scientific knowledge , and it is that nation which will be able to seize the more spectacular achievements of science in the industrial sphere"

Reviews

Viewpoint and Vision

New Pathways in Science. By Sir Arthur Eddington (Messenger Lectures, 1934.) Pp x+333+4 plates (Cambridge At the University Press, 1935) 10*s* 6*d*. net

THIS book is, from one point of view, a revision of the author's "The Nature of the Physical World" (1929); from another, it is a sequel thereto. The subjects treated are, in the main, the same, but the treatment is brought up to date and the underlying philosophy is re-presented so as to face more directly the attacks of criticism In a brief review, only passing mention can be made of the purely scientific aspects of the book, interesting though they are , the general outlook demands chief attention

The first thing that springs to notice is the extreme stability of the author's attitude His citadel has been attacked by men of science, philosophers of various schools, rationalists, religionists and nondescripts, and after making all due allowance for mutual cancellation in such a variety of onslaught, we should have thought that

sufficient unanimity of direction remained to cause, if not a breach in the walls, at least a modification of the method of defence It is not so Whatever change appears is a development of physical or astronomical theory, the philosophy remains the same This raises an interesting problem How comes it that a man, undoubtedly of exceptional insight, of universal interests coupled with wide and varied knowledge, a master alike of the most abstract processes of generalisation and the minutest details of application, and one gifted with extreme facility and grace of expression—how comes it, we ask, that such a man, having reached deliberate and apparently final decisions on fundamental matters, should find himself either misunderstood or opposed by almost every contemporary thinker who has considered the same problems? To this question the present book suggests a possible answer

We should perhaps have said 'answers', for there is a subsidiary reason, namely, the highly figurative language employed We are not insensitive to the charm of Sir Arthur's style—the music of the spheres is wonderful, but the words are a little indistinct We are carried on through image and metaphor and simile and anecdote by the most perfect of guides, and the experience is so delightful that we could scarcely wish it otherwise, but there are moments when we sigh for just one simple, dry-as-dust footnote to tell us what it all means His defence of this practice is that in non-technical books one should aim at using inexact language—a defence which might be less ineffective if he had anywhere expressed his philosophy except in such books In answer to a critic who pointed out that in "The Nature of the Physical World" the word 'space' occurs with four different meanings, he pleads that the word *has* those meanings—as though words had inherent meanings independent of the ideas they are to convey "We call it 'pain'," said the Frenchman, "We call it 'brot'," said the German, "We call it 'bread'," said the Englishman, "and it *is* bread"

This point is not so trivial as it may appear, for it exemplifies a very general characteristic which we believe lies close to the main source of Sir Arthur Eddington's nonconformity The late advances in physics which have greatly clarified the outlook of most philosophers of science with regard to fundamentals, seem to have led him into greater obscurity Accordingly he takes a viewpoint from which familiar distinctions are invisible and surface features have profound meaning We will try to make this clear.

In the nineteenth century the philosophical man of science, however obvious it seemed to him that his subjective experience was the source of all his knowledge, was forced by the character of the physics he professed to admit an objective external world of which his experience was only one aspect. That world was therefore at once the source and the creation of experience Thanks to relativity, this unsatisfactory position is now unnecessary We start with experience, pick out those elements which are common to all observers, represent them by concepts defined in such a way that, by the aid of whatever suitably defined subsidiary concepts are necessary, they relate together as many as possible of the common experiences, and the resulting logical network is the 'external world' In brief, we have all experience as our starting point, and a builder (reason) who incorporates as much experience as he can into the ever-growing structure of the physical world, that is all

Now how does Sir Arthur Eddington view the matter? Instead of thus resolving the nineteenth century dilemma, he makes confusion worse confounded From his summary on pp 257–58 of the allegorical first chapter, we extract the following ordered set of independent entities —(i) consciousness, (ii) phenomena of observation, (iii) nerves, (iv) theoretical physics, (v) the basal entities of physics (electrons, etc), (vi) the nature of the basal entities (which, however, plays no part in the drama, being 'essentially unknowable') With this extremely complicated machinery to manipulate, it is small wonder that he finds himself remote from ordinary thinkers their problems scarcely concern him—his seem remote from them He is like a man in Arizona who, looking horizontally at ground level, misses the Grand Canyon but sees an ant-track fundamentally cleaving the universe Let us see some examples of this anomalous valuation

Sir Arthur's attitude to the basal physical entities affords a conspicuous one Their degree and kind of 'reality', he tells us, are identical with those of sticks and stones He does not believe, however, "that the twoness of two electrons is a bit like the twoness of two apples", and while the preservation of individual existence by photons between emission and absorption "is a very obscure question" (p 38), he regarded, we recall, the similar question relative to the moon (p 226 of the earlier book) as meaningless These are not inadvertences, if they were we should be captious to mention them He would reaffirm these statements but declare that the differences in question were insignificant We are not surprised to find later (p. 226) that his search for a physical standard of length, "idealised, if you like, but not to the extent of having a different relationship to human experience from that which a physical object has", ends in the choice of "the radius of curvature of space-time". It is not asserted, be it noted, that

this entity can ultimately be expressed in the same terms as a physical object, it has the same "relationship to human experience" If Dr Johnson had only thought of kicking the radius of curvature of space-time, what a refutation of Berkeley we should have had!

The same characteristic appears in a very different setting in his treatment of the following problem, given as an example of a certain principle "If A, B, C, D each speak the truth once in three times (independently), and A affirms that B denies that C declares that D is a liar, what is the probability that D was speaking the truth?" A solution is outlined which appears not to be self-consistent, but we need not consider the solution—it is the attitude to the question that concerns us Let us, then, eliminate superfluities and restate the second datum as "A says that D lies" Sir Arthur's treatment effectively combines the knowledge of D's moral character with that of A's But is it not clear that such combination is purely fictitious? From our knowledge of D the probability is $\frac{1}{3}$; from our (independent) knowledge of A it is $\frac{2}{3}$ The results are inconsistent because the data are independent, we are effectively defining probability in different ways On form a certain horse becomes favourite at 5 1, his probability of success is $\frac{1}{6}$ Statistics show that the favourite wins, say, once in ten times, his probability of success is $\frac{1}{10}$. What meaning can there be in combining the two results? Yet such distinction of definition does not exist for Sir Arthur.

On the other hand, distinctions which to most of us seem trifling, or even fantastic, are for him vital. Perhaps the most striking instance is the question of the objectivity of "time's arrow". The whole trouble arises because Sir Arthur has more than one independent world, and he wants them to correspond Hence, feeling time's progress in consciousness, he must seek its counterpart in the physical world To realise the problem, he pictures a state in which immediate consciousness of earlier and later is lost and we must experiment to find whether we are getting older or younger. Abolition of memory is not what is supposed, for that would leave us without consciousness that time *could* go on: we must be aware that time has this property, but not know which way it goes. We must be reduced, in short, to a state of idiocy compared with which the mental outlook of Caliban would be clairvoyance

It is not to be supposed, however, that the problem with which Sir Arthur grapples so manfully does not exist. It is certainly real, but how different it appears from a normal point of view! Since the external world is built out of experience but does not contain the whole of experience, the going-on of time may or may not be in it We find on examination that it is, that is, phenomena in which it is an essential element belong to that part of our experience which we share with others If ever progression were so cruel as to desert experience, it would go out of the physical world also: we should deal with it exactly as we have dealt with absolute motion From this viewpoint the problem is simple, and there is no need to invent a Gilbertian situation to give it meaning

The relevance of this for our purpose, however, is not that change of viewpoint simplifies the problem, but that it does not destroy it For in this respect it agrees with all other such transformations in declaring that Sir Arthur has no hallucinations He may miss distinctions which exist, he may magnify distinctions which are shallow, but he never sees distinctions which are not there At the present time this has profound significance

Sir Arthur has lately placed before the scientific world a theory connecting relativity with quantum mechanics In common, we believe, with most, if not all, of our betters, we have failed to understand it, and the account in the present book does little to illumine the darkness We live in the hope that it will ultimately be transformed to natural co-ordinates. Nevertheless, if we were forced to express an opinion on whether it represented one of the greatest advances of a generation or a piece of sheer illusion, we should unhesitatingly choose the former alternative This decision would be made purely on external evidence Sir Arthur's past record and his consistent freedom from delusions, combined with his conviction that he has really unearthed something fundamentally important (a conviction which, unless we are greatly mistaken, is at the opposite pole from that which proceeds from self-deception) are positive indications which seem to us to outweigh the purely negative evidence arising from his inability to make the theory comprehensible. Such evidence, indeed, is largely discounted by the consideration that one who looks at everything abnormally would scarcely be expected to describe, in terms intelligible to others, something which only he as yet sees The question, of course, remains open, for such considerations as these are negligible compared with the evidence which the theory itself should yield; but while the theory yields nothing generally intelligible, they may at least serve to suggest an attitude towards it

In the meantime, we can enjoy to the full the more familiar fare which the present book provides It is unfortunate that Nature, having endowed a man with almost incomparable vision, should set him at an angle so widely divergent from that of other spectators of her drama. But

science does wonders in these days, and who knows but that ere long mental distances will be traversed with as much ease as physical ones? With this prospect in view we hope that in six years time the paper of the present volume will not have become so yellow as that of "The Nature of the Physical World" such books are worthy of better incarnation HERBERT DINGLE.

Standardised Drugs

The British Pharmaceutical Codex, 1934: an Imperial Dispensatory for the Use of Medical Practitioners and Pharmacists Pp xxv+1768 (London · The Pharmaceutical Press, 1934) 35s net

THE materia medica in use throughout the British Empire can be divided into two groups, those admitted to, and those excluded from, the "British Pharmacopœia", 1932 The second group is, on the whole, the more interesting, if only for the reason that the pharmacopœial drugs should be approaching the stage at which there is little more that can be said about their nature, composition and therapeutic value, though this is obviously not the case with such drugs as ergot and digitalis, whilst the unofficial drugs at the worst are declining into objects of historical medical interest, and at the best may be destined to attain pharmacopœial eminence in due course, or may even be the harbingers of therapeutic revolutions

It was a public-spirited desire to provide authoritative information regarding this newer materia medica which led the Pharmaceutical Society to publish the first "Codex" in 1907 and to issue new editions in 1911, 1923 and 1934. Drugs steadily become more varied and more complex and, in preparing this fourth edition, it has been necessary to distribute the work among six committees of experts. The success with which the work of these committees has been blended into a harmonious whole is especially noticeable in the monographs on crude vegetable drugs, which are now brief but clear and well-balanced statements, giving all the information the practising pharmacist is likely to require In spite of the recent activity in the chemical examination of vegetable drugs there remain a surprisingly large number with ill-defined components, or of which the activity cannot yet be assigned to any definite constituent

Though the Food and Drugs (Adulteration) Act requires a drug to be of the nature and quality demanded by the purchaser, it provides no standard by which the quality is to be determined. In these circumstances, the "Pharmacopœia" has become a presumptive standard for each of the drugs recognised in it, and it is no doubt hoped that the "Codex" will gradually acquire a similar position for the extra-pharmacopœial drugs it describes Both the "Pharmacopœia" and the "Codex" are already accepted as legal standards in certain parts of the British Empire Much work has obviously been done by the expert committees in providing the new "Codex" with standards "which experience has shown to be desirable as criteria of purity" and which "may be attained without undue difficulty or expense".

There are numerous appendixes, and special mention may be made of those on the determination of foreign matter in powdered vegetable drugs, hydrogen ion concentration, colloidal solutions and sterilisation, all subjects of outstanding importance in modern pharmaceutical practice

The old "Pharmacological and Therapeutic Index" is replaced by a "Pharmacological Index" (Appendix xiii) divided into drugs arranged in accordance with (*a*) their pharmacological action, (*b*) their use for a specific effect in certain diseases, the latter including most of the modern drugs evolved by chemotherapeutic investigations, the recent contributions to vaccine and serum therapy and those due to biochemical work on vitamins, hormones, etc

The most casual perusal of the volume impresses the reader with the amount and variety of analytical work now required in the manufacture and control of the enormous number of drugs and chemicals used in medicine, and it is not surprising that the Council of the Pharmaceutical Society should have considered it necessary to institute a post-graduate diploma in pharmaceutical analysis, for which, according to the official *Journal*, the first examination has been held recently

The proofs have been read carefully, and there are very few printer's errors The paper and the type have been improved, and the book opens fully and remains open, a desirable and not too frequent characteristic of books which, like this one, are intended mainly for reference

Vitalistic Biology and Education

Education and Biology. By J A. Lauwerys, with the assistance of F A. Baker. Pp xvi+207+4 plates. (London: Sands and Co, 1934.) 5s.

MANY thoughtful biologists, both in schools of various grades and in colleges and universities, are becoming increasingly disturbed in their minds concerning the relation of their teaching to the ideals and wider issues of education. This unease is not merely a state to be resolved by the more widely spread inclusion of biology in the curriculum, desirable though this be: it has

its roots in questionings of the philosophic perspectives of the subject itself and its presentation to the pupil Mr Lauwerys attempts to clarify the situation by considering the general problem and its practical issues, and as he is lecturer in the methods of science at the London Institute of Education, is deeply interested and widely read in the philosophic aspects of science, and has come under the humane influence of Sir Percy Nunn, his book is of absorbing interest His point of view throughout is that biology possesses its own concepts, technique and methods; the biologist must perceive the living organism as a concrete sensual whole with time and space relations, he must interpret his observations and results in biological concepts, and he must formulate a vitalistic philosophy of biology using "dynamic type" as a central concept For the teaching biologist this would involve not the abandonment of the usual subject matter but a fundamental alteration in the usual mode of presentation.

The author first attempts to sketch out his own vitalistic philosophy of biology, proceeds to a consideration of certain difficult problems which all teachers must face, such as the treatment of sex and the 'doctrine of evolution', and then discusses the subject matter of the syllabus and actual methods of teaching The last chapter deals with the laboratory and practical part of the course and contains particular applications of the earlier discussions Appendixes consist of an interesting plan showing the interrelationships of topics, a number of examples worked out to show the application to particular subjects of the method of approach discussed in the text and, finally, a number of bibliographies containing startling sins of omission and commission

Biologists will gain if they accord the author a respectful interest, even if this is not always a sympathetic one, for he has something definite to say and says it unusually well Many biologists, however, may find their patience wearing thin when reading certain portions of chapter iii, especially the discussion on evolution, where the author, both in text and references, seems to know little or nothing of twentieth century work Further, in many places, he seems to be writing from the point of view of a particular religious denomination, but it is to be hoped that this will not obscure the reader's view since, in the wider reaches of education, religious influences are still of primary magnitude, and in the immediate issue the author's vitalistic approach and philosophic attitude have no necessary connexion with religious tenets The book is a sincere attempt to deal with a very difficult and urgent problem, and it merits serious consideration by all who are interested in the teaching of biology.

Short Notices

Gmelins Handbuch der anorganischen Chemie Achte Auflage. Herausgegeben von der Deutschen Chemischen Gesellschaft. *System-Nummer 59*. *Eisen.* Teil A, Lieferung 6 Pp xxi+1167–1420. 41.50 gold marks Teil A, Lieferung 7. Pp xxvi+1421–1634 36 gold marks. (Berlin: Verlag Chemie G.m.b.H, 1934)

ALTHOUGH the definite compounds which iron forms with other elements comprise the subject-matter of vol. A on iron, many elements play such important parts in the chemistry of steel and cast-iron that it has been found advisable to deal separately with such associations of iron and non-metals as can conveniently be termed alloys. This plan has involved very little overlapping For example, whereas iron carbonyls are properly included amongst the compounds, iron carbide will be found in the present volume on account of its peculiar significance in relation to cast-iron and steel, and we find the phase-systems iron-sulphur, iron-selenium, iron-tellurium. iron-boron and iron-carbon successively described and illustrated with diagrams. Naturally greatest importance is attached to the last-named system. The iron-carbon diagram is set forth very clearly in the familiar compact form, but it has also been enlarged to cover two full pages in order to show the varying readings, sometimes amounting to more than 100° C, of numerous investigators This is followed by several pages of explanatory notes and references to the literature, so that an enormous amount of significant detail upon this very important and complex problem has been assembled in a fashion that should be invaluable to specialists The properties of iron carbide, which is so conspicuous a component of these mixtures, are then recorded in great detail in order to prepare the ground for the remaining sections, which deal with problems of solidification and crystallisation of molten steels and with special processes such as annealing, decarburisation, rolling, hardening, tempering and case-hardening.

The next part of vol A is an elaborate compilation of the magnetic and electrical properties of both pure iron and the commercial varieties. Among the topics discussed we find theories of magnetism, magnetic properties of the atom, magnetic intensity, permeability, hysteresis, etc., as well as electrical resistance, thermo-electric effects, dielectric constants and electrophotophoresis The literature of this section has been reviewed to June 1934, and a most useful feature in both parts is the incorporation in every section of a bibliography of general literature.

Über den Geschmackssinn der Biene: ein Beitrag zur vergleichenden Physiologie des Geschmacks. Von K. v Frisch (Zeitschrift für vergleichende Physiologie, herausgegeben von K. v. Frisch und A Kuhn, Band 21, Heft 1) Pp 156 (Berlin: Julius Springer, 1934.) 19 80 gold marks

PROF VON FRISCH'S studies on the senses of sight and smell in bees and on the means of communication between bee and bee in the hive are well known His earlier reports on the sense of taste are here presented in greater detail

The method used was to determine the 'threshold value' of solutions of sugars which were attractive to bees This value varied with the age of the bee and the availability of other sources of booty.

The number of sugars and allied compounds tested which are sweet to bees, is less than in the case of vertebrates Such substances as saccharin are either neutral or repellent An attempt was made to correlate chemical constitution with taste but without marked success The high concentration of sugars in their natural food has made bees relatively insensitive to sweet taste Conversely, those plants which have afforded the more profitable nectar of higher concentration have been more thoroughly pollinated, giving a bigger yield of seed

Substances distasteful to bees were tested in a solution of cane sugar of known attractiveness. The repellent action of acids did not depend solely on the titration acidity. The theory is advanced that weak acids, not being fully dissociated, have a reserve of hydrogen ions, which replace those used up in the taste process This makes them appear more effective than strong acids of the same hydrogen ion concentration. This phenomenon is more marked with higher concentrations of acid

The author concludes that bees can distinguish the four flavours, sweet, salt, acid and bitter D M.

Modern Acoustics By Dr. A H Davis Pp. xi+345 (London G Bell and Sons, Ltd., 1934.) 26*s*. net

DR DAVIS'S treatise on modern acoustics has more than fulfilled the expectations aroused by the announcement of its early appearance The author has, very wisely, interpreted the title of the book strictly and, by saving space which might otherwise have been devoted to fundamental dynamical theory and to such classical problems as the vibrations of bars and strings, has been able to provide us with very full, lucid and well-documented accounts of the remarkable advances in acoustics made in the present generation. Modern methods of measurement of intensity, frequency and reverberation, the development of the notion of acoustical impedance, the ear and hearing, the acoustics of auditoriums, noise, its measurement and its suppression—this list by no means exhausts the topics treated in a volume which no advanced student of the science can afford to ignore.

The book, so far as the mathematical side is concerned, deals with results rather than with mathematical developments, and such matters as a detailed consideration of recent extensions of Rayleigh's principle scarcely fall within its purview. A. F.

The Flow of Water in Pipes, Sewers and Channels, over Weirs and off Catchments By G. B Williams. Pp. 76 (London. Chapman and Hall, Ltd, 1934) 10*s* 6*d*. net.

THE author of this publication, who was formerly Chief Engineer in the Public Health Department of the Government of Bengal, has embodied the results of his Indian experience and practice in diagrammatic form, using the coefficients which he has found most suitable for adoption with the classical formulæ of Manning and Kutter for discharges and velocity of flow in pipes and open channels, and the Francis formula for weirs There are 41 full-page diagrams, approximately 9 in by 6 in, dealing with this part of the subject, and thereafter five more diagrams relating to rainfall intensity, the relationship between rainfall and run-off and to flood discharges from catchment areas in India up to 1,000 square miles in extent

It is impracticable within the limits at disposal to describe in greater detail the information obtainable from the tables, they will undoubtedly be of service to the practising civil engineer who has to deal with questions of water supply, land drainage and sewage disposal, especially in circumstances similar to those in the author's experience The graphs are easy of interpretation and will save a great deal of calculation, being capable of supplying results for a wide range of conditions It has been the author's object to supply a need which he has felt for a tabular reference compilation of this kind not to be found in technical treatises on the subject generally B C

Das Brillenglas als optisches Instrument von den wissenschaftlichen Mitarbeitern an der Optischen Werkstätte von Carl Zeiss, Jena Von Prof. Dr Moritz von Rohr und Dr Hans Boegehold Mit einem Beitrage von Dr Hans Hartinger Völlige neubearbeitung des Buches "Die Brille als optisches Instrument" Pp. x+281. (Berlin: Julius Springer, 1934) 25 80 gold marks.

PROF. VON ROHR has directed the Jena school of opticians for many years, and the treatise now before us is a completely revised edition of his book, "Die Brille als optisches Instrument". It is therefore of great interest to all interested in ophthalmic optics Apart from some introductory remarks on spectacle lenses for special purposes, the book is divided into four main parts. The first deals with anastigmatic lenses, some attention being paid to toric and to prismatic lenses. The second portion treats the problems of astigmatic lenses, and the third those of chromatic aberration. The mathematical treatment is easy to follow and graphs are effectively used. The last main section discusses problems of the alterations in field conditions produced by lenses.

Throughout the book the authors add delightful short sections on the historical aspects of the problems treated, and they fittingly conclude this excellent work with an account of the development of our knowledge of the spectacle lens and some notes on the training of opticians.

Possible Value of Inhalation of Carbon Dioxide in Climbing Great Altitudes

By SAMUEL B CHILDS, JR, HANNIBAL HAMLIN and PROF YANDELL HENDERSON, Laboratory of Applied Physiology, Yale University

MOUNTAIN sickness is a form of asphyxia due to the diminished partial pressure of oxygen at great altitudes The functional disturbances in this disorder are, however, not merely anoxial, but are largely the expression of a secondary and almost equally important deficiency of carbon dioxide in the blood and tissues Deficiency of oxygen induces hyperpnea and acapnia · that is, overbreathing and the resulting deficiency of carbon dioxide Acapnia in turn induces subnormal respiration and a continued or even increased deficiency of oxygen Haldane, Priestley and Douglas[1] demonstrated the correctness of Miescher's somewhat poetical formulation : "Over the oxygen supply of the body carbon dioxide spreads its protecting wings "[2] Henderson[3] confirmed the importance of the relation between the two gases in respiration when he found that it was possible to produce so great a deficiency of carbon dioxide by over-ventilation of the lungs that thereafter an animal may die of lack of oxygen with no effort to breathe

On Pike's Peak in 1911, Douglas, Haldane, Henderson and Schneider[4] made a number of observations on muscular work in which these relations were strikingly illustrated One of them was as follows · a member of the party whose respiratory centre was peculiarly sensitive (as indicated by the fact that he acclimatised more rapidly than any of the others) exercised by walking as rapidly as possible for a quarter of a mile up the cog railway, grade 1 in 5 While walking, he experienced an almost intolerable panting , but when he stopped to get his breath, he very quickly stopped breathing entirely for a few seconds, and then developed alternating hyperpneas and apneas Insufficiency of oxygen was clearly the condition inducing the excessive breathing and pumping out of carbon dioxide, and the consequent apnea. The apnea in turn intensified the anoxia and induced another period of overbreathing

As the work of climbing would not have been an excessive exercise for this individual at sea-level, it is probable that the amount of carbon dioxide produced was insufficient to maintain a continuance of vigorous breathing, except during the time that it was reinforced by acute oxygen deficiency.

The cause of the overbreathing was indicated by another observation. Merely squeezing a rather stiff rubber bulb with one hand as vigorously as possible, without other exercise, until the muscles of the forearm were tired, induced such excessive breathing that cessation of the manual activity was followed by apnea and then by alternating periods of overbreathing and apnea This observation accords with the classic investigations of Geppert and Zuntz[5] on animals It indicates, as they concluded, that some respiratory stimulant, other than carbon dioxide, is formed in vigorously active muscles, or under a deficiency of oxygen, and is carried by the blood to the respiratory centre, or the closely connected sinus caroticus For reasons that we will not now stop to discuss, we do not believe that this substance, 'respiratory X'[6], is lactic acid, but rather that it is some specific hormone that increases the sensitivity of the respiratory centre to carbon dioxide

Recently, Winterstein[7] has suggested that inhalation of a small amount of carbon dioxide might be helpful in maintaining respiration and promoting oxygen absorption at great altitudes In order to test this idea, two of the writers of this article, both vigorous young men, spent a few days on Pike's Peak during the summer of 1934

As the time on the Peak available for this investigation was short, the observations were confined to the subject of the acapnia which is the result of oxygen deficiency, and which in turn aggravates that deficiency For this purpose small cylinders were provided, charged with enough liquid carbon dioxide to form 400 litres of gas The flow of the gas was controlled and adjusted by a small, but accurate and light, reducing valve and flow gauge The whole apparatus* weighed only 4 kgm. and was carried at one side suspended by a strap across the opposite shoulder The flow was usually set at 2 litres per minute, and was conducted through a rubber tube to an open mask with wide holes to the outside through which the wearer breathed the outside air without the slightest impediment During expiration the gas was thus blown away and wasted , but during inspiration it mixed with the inspired air The amount of carbon dioxide inspired was therefore only about 1 litre per minute If the wearer of the apparatus breathed 50 litres of air per minute, the carbon dioxide was thus diluted to 2 per cent With a respiration of 20 litres per minute, the dilution would come to one in twenty or 5 per cent

* We are much indebted to the Ohio Chemical and Manufacturing Company for placing this very efficient apparatus at our service It proved ideally convenient

The two members of our party had been on the Peak for only a couple of days, but were sufficiently acclimatised to be comfortable Three young men, who were employed in the hotel on the summit of the Peak (14,100 ft) and were fully acclimatised, also performed the tests Each of these five men made four experiments, wearing the apparatus and walking a distance of 250 yards up the cog railway, grade 1 in 5, in two minutes. The work amounted to lifting the man's body and the 8 lb. apparatus 150 ft vertically On one day the tests with inhalation of carbon dioxide were made first, and an hour later exactly the same exertions were made while wearing the apparatus with the gas shut off On the next day the control exertions were made first, and those with inhalation of carbon dioxide were made an hour later

The results on all five of the men were closely similar. None felt either the exertion of the respiratory strain to be at all increased by the inhalation, but rather the contrary All noted the greater regularity of their breathing with the gas on than with it turned off. This subjective evidence was also in accord with objective findings from pulse counts and measurements of arterial pressure made immediately after the climbs The average pulse rate was the same after the ten climbs in which carbon dioxide was inhaled than it was after the ten climbs without the inhalation: 126 heart beats per minute. Without the inhalation the average rise of systolic arterial pressure was 67 mm, namely 108–175 With the inhalation it was only 50 mm, namely, 110–160 Diastolic arterial pressure, instead of rising, was slightly lower after the exertion than before—lower by an average of only 1 mm without inhalation and 3 mm. with the inhalation The alveolar carbon dioxide was lowered 0 5 per cent in the control test without inhalation; but was 0·5 per cent higher after the exertion than before when the inhalation was used.

These effects are not large, but on the whole the evidence indicates that the exertion was made with somewhat less strain on the heart and respiration with inhalation of carbon dioxide than without. The reason appears in the fact that excessive loss of carbon dioxide was prevented. On the contrary, the alveolar carbon dioxide was raised. The supply of oxygen was thus protected and its utilisation aided by the influence of the carbon dioxide upon the Bohr-Haldane[1] relations of the blood gases.

In addition to these experiments, observations were made upon thirty tourists who were more or less affected with mountain sickness and who, out of several hundred visitors to the Peak, submitted to be treated and examined. All had made the ascent either by the cog railway or by automobile. In most of these cases cyanosis or pallor, dizziness, headache and nausea had developed when they walked about on the summit or came into the warmer air of the lunch room. In extreme cases, periodic breathing, confusion, muscular cramps and twitchings, and low blood pressure or even fainting occurred before the inhalation was administered

The inhalation was usually continued for only 2–3 minutes at a time The effects were in most cases subjectively beneficial. None felt the worse for it The colour of their lips was distinctly improved Respiration was in all cases changed from irregular, or even intermittent, to a regular and deep rhythm, but was seldom increased in rate. Systolic arterial pressure was not altered significantly, that is, only from an average of 105 mm to 103 mm The average diastolic pressure, on the contrary, was raised from 62 mm. to 69 mm, while the pulse-rate was decreased from an average of 92 to 82 per minute Considering that these figures were the averages on thirty subjects, they are, we think, significant of distinct benefit from the inhalation

The only persons whose conditions changed disadvantageously were two men who had ascended the peak on foot, arriving in a state of exhaustion, who developed conditions verging on collapse just as the inhalation was started. Their condition appeared so serious that instead of continuance of inhalation, arrangements were made for them to be immediately conveyed down the mountain. It is probable that their collapse was due to their exhaustion and that it would have developed anyway, as is often the case, as soon as they stopped climbing. It seemed safer, however, not to continue the inhalation, lest it should be blamed for their subsequent condition.

Our conclusions are that, at least up to an altitude of 14,000 ft. (barometric pressure 450 mm) inhalation of a small amount of carbon dioxide with the inspired air is distinctly beneficial in protecting against both acapnia and anoxia during and after vigorous physical exertion. As the effects were even better on those who had made no great exertion, we suggest that such an inhalation might be of considerable value also for passengers travelling by air at altitudes up to at least 14,000 ft Tests at greater altitudes on mountaineers and aviators are deserving of trial For this purpose, carbon dioxide has one advantage over oxygen: much less is required.

Light-Waves as Units of Length

By DR. W. EWART WILLIAMS, King's College, London

THE standard of length measurement in any age gives us a fairly true picture of the general requirements of the time. King David of Scotland (c. A.D. 1150) ordained that the Scotch inch should be the mean measure of the thumbs of three men, "an merkle man, an man of measurable stature and an lyttel man", the thumbs being measured at the root of the nail. The history of the transition to our present-day standards was admirably related by Sir Richard Glazebrook in his Guthrie lecture to the Physical Society in 1931.

For more than a century, scientific men have been attracted to the idea of establishing the unit of length on the basis of some natural standard, as in the famous dream of Arago[1], "une mesure susceptible d'être reproduite quand même des tremblements de terre, des cataclysmes épouvantables viendraient à bouleverser notre planète et à détruire les étalons prototypes gardés aux Archives". The metre was originally intended to be one millionth part of a meridional quadrant of the earth, and the yard, if ever lost, was, according to the Weights and Measures Act of 1824, to be replaced by reference to the length of a pendulum (in vacuum) beating seconds at sea-level in London. Various difficulties finally led to the adoption of purely arbitrary units, and the metre and yard became the distances between marks on bars kept at Sèvres in France and at the Standards Office of the Board of Trade in London.

The idea of employing a light-wave as the standard of length was frequently proposed during the nineteenth century. Clerk Maxwell[2], in an eloquent address to the British Association at Bradford in 1873, pointed out that: "Each molecule therefore throughout the universe bears impressed on it the stamp of a metric system as distinctly as does the metre of the Archives at Paris or the double royal cubit of the temple at Karnac". Pierce[3] in 1879 attempted a precision measurement of the wave-lengths of the sodium lines, and with improved diffraction gratings the work was repeated by Bell[4] in 1887. The first description of a method that would ensure sufficient accuracy was given by Michelson and Morley[5] in 1887 and in more detail in 1889.

With the assistance of Dr. Gould, the American representative on the newly-formed International Committee of Weights and Measures, Michelson[6] was able to use his new type of interferometer, and in collaboration with Benoit, succeeded in making a direct determination of the number of waves of the red radiation of cadmium contained in the metre. In the usual Michelson interferometer, the light first falls on a half-silvered mirror so that the reflected and transmitted beams, of approximately equal intensity, are mutually perpendicular. The beams are then reflected back on their own paths by two fully silvered mirrors. With equality of optical paths and a slight tilt of either mirror, white light fringes can be observed in the beam emerging from the semi-silvered plate.

For the purpose of the metre determination, one of the fully silvered mirrors was replaced by an 'étalon' consisting of two parallel mirrors, one above the other in a stair formation; nine such units, with mirror separations ranging from 0.39 mm. to 10 cm., were constructed so that the labour and uncertainty of counting a large number of fringes might be avoided. The exact details need not be entered into here, but it should be clearly emphasised that although only the number of fringes in the smallest unit had to be actually counted, the method was such that the number of wave-lengths in the (double) path of the largest étalon was obtained to within a few hundredths part of one fringe. A mark on this étalon was placed in line with one of the fiduciary marks of the working standard metre by means of a travelling microscope, and white light fringes were obtained in the upper étalon mirror by suitably adjusting the reference mirror of the interferometer. When the unit was moved until the fringes appeared in its lower mirror, it meant that the étalon had been displaced by exactly its own length; this procedure was repeated, in all ten times, so that any error in the determination of this basic étalon is increased tenfold. Finally, the small difference between the alignment of the second metre mark and the new position of the étalon mark is measured by means of a travelling micrometer. This distance, of the order of a few hundredths of a millimetre, is so small that any uncertainty in the previously known value of the wave-length can have no influence on the result. It should be mentioned that the working standard metre has also to be compared with the available national standards, and these in turn have been similarly compared with the prototype metre itself by means of travelling microscopes in an arrangement that is termed a line comparator.

The fringes given by a Michelson interferometer are invariably broad, however monochromatic the source may be; in effect, we have two virtual sources, so that the bright and dark portions have equal width.

Hamy[7] in 1897 discovered the important fact that multiple reflection made it possible to obtain considerably narrower fringes with a corresponding increase in the resolving power He constructed an interferometer consisting of a thinly silvered plate mounted in front of, and parallel to, a fully silvered mirror When the fringes are observed by transmission through two semi-silvered surfaces instead of by reflection, the arrangement constitutes the Fabry-Perot interferometer, which has found wide application in the study of the structure of spectral lines

Benoit, Fabry and Perot[8] used the latter instrument as the basis of an entirely distinct method of standardising the metre in terms of wave-lengths. The order of interference of the circular fringe system of an étalon with a plate separation of approximately 6·25 cm was first determined by means of Benoit's fractional part method, since the wave-lengths of a number of lines were already known with sufficient accuracy for this purpose. This order of interference is the number of waves contained in the double path of the étalon

The next step was to obtain the path difference (in wave-lengths) between a single reflection in a similar unit of twice its size, and a double reflection in the basic unit the value of which is already known This was accomplished by arranging the units in line, so that a beam of white light could be passed through both and the well-known Brewster fringes obtained The exact difference was found by introducing a previously calibrated wedge into the beam. The process was repeated with successively larger units until the 100 cm standard had been reached.

Instead of attempting to set the cross-wires of the microscope comparator on the silvered edges of the plates when comparing it with the working metre, the measurements were made to rulings on the edges of the plates close to the surface and similar in character to the marks on the metre By means of a subsidiary experiment, probably the most ingenious and beautiful example of fine experimental work in the whole field of metrology, the correction factor, which is the total distance from these marks to the effective reflecting planes, was determined with the, greatest possible precision.

The now classical work of Benoit and his collaborators, completed in 1907, was generally considered to be so accurate that a further determination was felt to be unnecessary. The wave-length of the red radiation of cadmium then found has been accepted and still remains the spectroscopic standard of length of the scientific world.

As a step towards the eventual adoption of a wave-length as the fundamental unit of length, the International Committee of Weights and Measures[9] urged the various national laboratories to carry out similar investigations using their own national standards.

The first results were those of Watanabe and Imaizumi[10]. Their apparatus, constructed by Hilger, was almost identical with that of Benoit, Fabry and Perot A difference of 0·002 A was initially observed between the values of the wave-length of the red line as determined from the two Japanese standards No 10 and No 20 Agreement was obtained when these prototypes were later compared with the International sub-standards at Sèvres, and fresh values were found for their exact individual length

The results of a determination carried out at the Physikalische Technische Reichanstalt, Berlin, have been given by Kosters[11]. The details of the method have not yet been given, but presumably, in view of the earlier intercomparisons of the cadmium and krypton wave-lengths described by Weber and Lampe[12], the method is based on Kosters's application of the Twyman and Green[13] interferometer. This consists of a modification of the Michelson instrument, in which the straight localised fringes are observed by using a point source at the focus of a lens, the eye replacing the eyepiece of the telescope

Sears and Barrell[14], of the Metrological Department of the National Physical Laboratory, have recently published the preliminary results of a systematic investigation of the problem extending over the last ten years A description of the actual apparatus has been previously given[15]. As will be seen in a later section in which the various results are analysed, the work is of the greatest importance, and not only the authors but also the Laboratory and its directorate deserve to be congratulated on the initiation and planning of such a comprehensive programme, the first stage of which has been completed

The authors have approached the problem from an entirely different angle; instead of setting themselves the problem of finding the number of waves contained in the metre, they have primarily determined the number contained in standard gauges of approximately one metre length. This they can find with an accuracy far exceeding that possible in a direct metre determination, so that the lengths of various other gauges (in terms of wave-lengths) can be ascertained with a precision hitherto considered impossible.

The first part of the method is basically that of Benoit, Fabry and Perot. The number of waves in a $\frac{1}{16}$ or a $\frac{1}{9}$ metre étalon is determined and the unit is used for direct comparison with a $\frac{1}{4}$ metre étalon by means of Brewster's fringes The step-up of four or three times instead of the

double step formerly used only involves a slight reduction in the clearness of the fringes. The calibrated wedge is omitted and the exact multiple of optical paths is obtained by tilting the larger unit, a method due to Fabry and Buisson[16].

An X-section gauge, the ends of which are optically parallel, is mounted inside the third étalon, which has to be slightly longer than a metre in order to accommodate the metre gauge. The Brewster fringes, given by three reflections in the intermediate standard and one in the larger unit, are observed in turn through each of the four channels or apertures formed by the X-section. Thus the mean length A of the largest étalon in wave-length units becomes known. The ends of the X-gauge do not touch the half-silvered étalon surfaces; the path differences B and C between the polished ends of the gauge and the silvered surfaces are determined by means of the circular Hamy fringes using Benoit's fractional part method. The *optical* length of the gauge is therefore $A-B-C$ wave-lengths, and its mechanical length is also known provided the phase change on reflection at the gauge surfaces is determined by a subsidiary experiment. This has been the primary purpose of the investigation.

In order to obtain the number of waves in the metre, an auxiliary gauge approximately half an inch shorter is employed, together with two further half-inch end gauges at the centres of which fine lines are engraved. If a half-inch gauge is wrung in contact with the auxiliary, a metre end standard is obtained which can be compared directly by interferometric methods with the X-section gauge. When both blocks are wrung, one on each end of the auxiliary, the composite gauge forms a metre line standard which can be compared with the national standard in a line comparator. By taking observations with the blocks contacted in all possible ways, the effects of slight irregularities and differences in the blocks and their bisecting lines are eliminated.

In the determination of the yard, the same étalons were used but the X- and the auxiliary gauges were 36 and 35.5 in. respectively, so that the differences B and C were therefore much greater.

Reference should also be made to the determination of the yard by Tutton[17]. The method involved the actual counting of the number of fringes in a distance of $\frac{1}{16}$ in. By an ingenious system of multiplication, the number of wave-lengths in the yard is determined by means of the Tutton wave-length comparator. The basic unit is, however, too short to yield sufficiently accurate results. This can be seen from the fact that temperature and pressure corrections for the basic unit are negligible, while they are applied to the greater lengths determined in terms of this unit. On the other hand, the accuracy is considerably greater than the one part in fifty thousand which a casual inspection of the method seems to imply.

For the sake of completeness, it might be recorded here that the writer[18] has proposed an entirely different method whereby the length of a metre gauge in the wave-lengths may be directly obtained from two observations. A suitable reflection echelon is to be used and any errors due to optical multiplication are eliminated.

Obituary

PROF. M. I. PUPIN

BY the death of Michael Idvorsky Pupin in New York on March 12 at the age of seventy-six years, we lose a mathematical physicist who has played an important part in engineering progress since the end of last century. The son of Serbian peasants, he emigrated at the age of sixteen years to New York, where he started to earn his living with only five cents in his pocket. After many struggles, during which he supported himself by manual labour, he gained free tuition at the entrance examination to Columbia University in 1879 and distinguished himself by winning many prizes both for his studies and at athletics. After graduating, he became a naturalised citizen of the United States.

Pupin was the first holder of the John Tyndall fellowship at Columbia. He elected to complete his training at Cambridge, England, being attracted by the prospect of studying under Clerk Maxwell and learning about his electromagnetic theory of light. Marion Crawford, the novelist, gave him a letter of introduction to Oscar Browning of King's, but he was away on his summer vacation. Pupin also had a letter of introduction to W. D. Niven, a tutor of Trinity College, who asked him what was his object in coming to Cambridge. He replied that he wanted to study under Clerk Maxwell, and was very surprised to learn that Maxwell had been dead for four years.

Before settling down at Cambridge, Pupin went to

his native village, Idvor, in Hungary, to see his parents On the way he stayed at Lucerne and was lucky enough to climb to the top of Titlis without accident When he returned to Cambridge he entered King's College and studied mathematics under Routh The present writer remembers seeing him there, and was impressed by his striking but un English appearance. Although he enjoyed Routh's lectures tremendously, Pupin had gone to Cambridge to study physics, and in his interesting autobiography entitled "From Immigrant to Inventor", published in 1923, he says that he thought Prof J J Thomson was too young to teach him much, and he was suspicious of Lord Rayleigh because of his title Later on, he had the greatest admiration for them both

After a two months holiday at Corrio in the Isle of Arran, where he read Faraday's "Experimental Researches", Pupin went to the University of Berlin and studied under Helmholtz and Kirchhoff, obtaining a Ph D degree On his return to New York he was appointed to a teaching post at Columbia University, was afterwards appointed adjunct professor of mechanics, and then professor of electro mechanics in 1901

In 1896 Pupin discovered secondary X ray radiation and invented in the same year means for short exposure X ray photography, by interposing a fluorescent screen before the photographic plate He invented also improvements in multiplex telegraphy and in methods of tuning for electrical resonance His most important invention was in connexion with long-distance telephone communication. By means of inductance coils placed at pre-determined intervals of the transmitting line, he greatly extended its range. In almost every country in the world 'Pupin coils' are used, and the enormously rapid development of long-distance telephony during this century has been due mainly to the use of these coils His first paper on the subject was published in the *Journal of the American Institution of Electrical Engineers* of March 22, 1899

Although an American citizen, Pupin will long be remembered by thousands of his former countrymen in Serbia—now Yugoslavia He founded the Serbian House in New York, and fathered and cared for thousands of poor immigrants He gave princely contributions to the Serbian Red Cross, to refugee funds and to many others, and his ample fortune, made mainly from his tele-communication inventions, was sorely diminished At Columbia University he was much esteemed and held in affection by the students He was a member of the executive committee of the National Research Council, a fellow of many scientific societies and an honorary doctor of Columbia and Johns Hopkins Universities.

A R

PROF. H. A. GILES

WE regret to record the death on February 13 of Prof. H. A. Giles, formerly professor of Chinese in the University of Cambridge. Herbert Allen Giles was born on December 8, 1845, the son of Dr. John Allen Giles, well-known to many generations of students of the classics as a translator. He was educated at Charterhouse and in 1867 joined the consular service in China, being appointed to Tientsin after a probationary year at Peking He retired from the service in 1893, returning to England, and in 1897 was appointed professor of Chinese at Cambridge He held this chair until 1932 when he retired, having done much to foster the study of the Chinese language in the University, and secured its recognition in the 'Little go' in place of Latin or Greek for natives of Asia.

Giles laid the foundations of his scholarship in Chinese during his probationary year in Peking Within a few years of his appointment to Tientsin, his knowledge of China had progressed so far as to enable him to write with authority on many sides of Chinese life and culture in the *Celestial Empire* He had also begun work on his monumental Chinese-English dictionary. This indeed was to prove his *magnum opus* It appeared in parts and in this form was completed in 1892 A new edition, revised and enlarged, appeared in 1912 It won him world wide recognition as the first European authority on the Chinese language, and in 1911 was awarded the Prix St Julien of the French Academy Its pre eminence in scholarship, however, should not be allowed to obscure the fact that Giles's knowledge of every side of Chinese life and culture was profound. Nowhere, perhaps, does this come out more clearly than in Giles's lighter works, and his "Strange Stories from a Chinese Studio" and "Quips from a Chinese Jest Book", no less informative than they are amusing, with their instructive notes and comments, might well serve as an introduction to most aspects of the many-sided Chinese mentality.

From 1870 onward, Giles was busily engaged, in such leisure as his consular duties afforded, in studying and in writing on the life, art, religion, language and history of the Chinese people A long list of substantial and authoritative works stands to his credit, of which the best known, next to his dictionary, is "A Chinese Biographical Dictionary". His achievement was recognised by many honours, among which may be mentioned the Order of Chia Ho, conferred by the Chinese Government, the award of the triennial gold medal of the Royal Asiatic Society and honorary degrees from the Universities of Oxford and Aberdeen

WE regret to announce the following deaths .

Prof J J R Macleod, F.R S., regius professor of physiology in the University of Aberdeen, formerly professor of physiology in the University of Toronto, on March 16, aged fifty eight years

Prof B M Wilson, professor of mathematics in University College, Dundee, formerly lecturer in pure mathematics in the University of Liverpool, on March 18, aged thirty-eight years.

Major-Gen. Sir Richard M. Ruck, of the Royal Engineers, known for his scientific work in submarine mining, chairman of Council of the Royal Aeronautical Society from 1912 until 1919, on March 18, aged eighty-three years.

News and Views

Centenary of the Geological Survey of Great Britain

THE Geological Survey of Great Britain is the oldest national geological survey in the world, having now been in active existence for a hundred years. It owes its inception to the private enterprise of the late Sir Henry Thomas De la Beche, who became its first director. Geological material was quickly accumulated and De la Beche was compelled to ask for museum accommodation. This was provided in a house in Craig's Court, Charing Cross, where it was opened to the public in 1841, as the Museum of Economic Geology. In 1851, the Museum was transferred to Jermyn Street, where it has continued until recently. For many years past, however, the space available has been inadequate, and it has been impossible to display to full advantage the very extensive collections of rocks, fossils and minerals in the possession of the Survey and Museum. In 1912, the Bell Committee recommended the transfer of the Museum and Survey to a site in South Kensington next to the Natural History Museum, but no action was taken until the Museums Commission met in 1927. The Government then agreed to the transfer, and the new building was completed by H.M. Office of Works in 1933. Occupation by the Geological Survey was, however, delayed by its utilisation as the meeting place of the World Economic Conference, 1933.

Opening of the New Museum of Practical Geology

IT is now announced that the new Museum of Practical Geology will be formally opened next July. Advantage has been taken of this to arrange a joint celebration of the centenary of the Geological Survey and the opening of the new Museum. In the new Museum at South Kensington ample accommodation has been provided to display the exhibits in a building specially designed to meet modern museum requirements. New material has been acquired from many sources and the extent and scope of the exhibits has been enlarged. For the past three or four years, geologists of the Survey and Museum have been mainly engaged in rearranging and bringing up to date the collections, their normal field work being subordinated to the needs of the Museum. At the back of the Museum new offices have been provided for the Geological Survey, together with modern laboratories for the prosecution of petrological and mineralogical research. Enlarged accommodation has been provided for the Library and collection of maps which, as in the past, will be available for consultation by the public. The Museum is to be opened by the Duke of York on July 3. On July 4 there will be a morning reception of delegates to the Centenary, followed by an address by the Director of the Survey on the history and functions of the Geological Survey of Great Britain. On the evening of July 4 there will be an evening reception by H.M. Government. Excursions to several of the classic areas of British geology follow immediately after the meetings. It is expected that a large and representative gathering of geologists from all parts of the world will be present for the celebration.

Dr. J. Chadwick, F.R.S.

DR. JAMES CHADWICK, fellow of Caius College, Cambridge, and assistant director of research in the Cavendish Laboratory, has been appointed to the Lyon Jones chair of physics in the University of Liverpool as from October 1 next, in succession to Prof. L. R. Wilberforce, who retires at the end of the present session. Dr. Chadwick is one of the most distinguished of the younger physicists in Great Britain. His early work on α, β- and γ-radiation led to the experimental proof of Moseley's deduction that the charge on the nucleus was equal to the atomic number. Then, in association with Lord Rutherford, he carried out investigations on the anomalous scattering of α particles by light elements, which gave information on the size and structure of the nucleus of the atom, while another line of work demonstrated the artificial transmutation of certain lighter elements by α-particle bombardment. Improvements in the technique of counting such particles led to the discovery of definite nuclear α particle and proton levels. The obscure effects observed by M. and Mme. Curie-Joliot when beryllium was bombarded with α-particles were investigated by Dr. Chadwick, and immediately he recognised that they could be explained by assuming the ejection of a particle having mass but no charge. This assumption he quickly proved in a brilliant series of experiments, and a new elementary particle, the neutron, which has proved of wide importance in investigations on atomic structure, was made available to the physicist. The value and originality of Dr. Chadwick's work has been recognised by his election to a fellowship of the Royal Society, by the award of the Hughes Medal of the Society in 1932 and other distinctions.

Racial History of Britain

A LETTER to *The Times* of March 13 puts forward on behalf of the Royal Anthropological Institute proposals for a comprehensive survey of the racial history and physical constitution of the inhabitants of Britain—a matter in which action is long overdue. It is a remarkable fact, and one which was not generally appreciated until necessity arose during the War, that so little should be known of the physical characters of the British population as a whole. The racial character of the British peoples in prehistoric and early historic times, as preserved in skeletal remains in museums, has received attention from time to time, but piecemeal; and more or less extended investigations of the present population have been carried out in parts of Scotland, Wales, England and Ireland; but no organised attempt has been made to correlate this material or to extend it systematically. The proposals now put forward

provide for both the examination of the skeletal material preserved in museums and anatomical collections and the measurement by trained observers of groups of the existing population all over the country Arrangements will also be made for the reduction and digestion of the material when collected, and for its publication

THE projected survey is an object which is deserving of strong public support Not only will the results be of the greatest scientific importance, as they will fill a gap in our knowledge of the composition of the British people which is much to be deplored, but they will also afford data of great significance, and from some points of view essential, in the consideration of a number of social and medical problems The survey will involve expenditure on instruments, travelling for purposes of observation and publication, towards which contributions are invited from the public in an appeal supported by, among other signatories, Lord Onslow, Lord Raglan, Lord Meston, Sir Richard Gregory, Sir Henry Wellcome and the Rev Edwin Smith, president of the Royal Anthropological Institute Contributions should be addressed to the Treasurer, Royal Anthropological Institute, 52 Upper Bedford Place, London W C 1

Expedition to New Guinea

PLANS for the exploration of the country in the neighbourhood of the Sepik River in the mandated territory of New Guinea, which have been in preparation for some time, are now approaching completion , and Mr G M Dyott, the leader, will leave shortly with two other members of the expedition for Australia, where he will be joined at Sydney by Mr H L Williams, the Australian anthropologist, who will complete the personnel of the party For some time past, the exploration of the Sepik River country has been an object of ambition of anthropologists and geographers alike The greater part of it is entirely unknown Last year, Mr E. W P Chinnery, in the course of an official tour of duty as Government anthropologist, penetrated to the eastern boundary of the unknown territory He reached the summit of Mount Hagen, and in his reports records how from a lofty plateau there he was able to look out over this country

MR. CHINNERY came into touch with hitherto undescribed peoples having many remarkable features in their culture, who were still living in the stone age (see NATURE, **134**, 328 ; 1934). In the account of his experience which he has since published, he describes signs of occupation in the unvisited tableland below, which point to a system of cultivation differing from anything previously recorded in New Guinea. Mr. Dyott's expedition, in addition to making a plane-table survey of the country traversed, will devote special attention to the culture of the peoples in the Sepik area It is also hoped to obtain conclusive evidence of the existence of the so-called 'devil-pig', a cloven-footed graminivorous animal, of which Mr. Monckton, formerly a resident magistrate in New Guinea, claimed to have observed the tracks, but of which knowledge otherwise rests on the report of the Papuans They fear it greatly The expedition is supported by the Australian Commonwealth Government and the Royal Geographical Society The collections which the expedition hopes to make will be divided between the Pitt Rivers Museum, Oxford, and certain institutions in Australia

Vertical Take-off with the Autogiro

SEÑOR DE LA CIERVA, lecturing before the Royal Aeronautical Society on March 15, made the first public announcement of the fact that he has produced a type of his autogiro that has achieved direct lift off the ground without any forward run This was shown by the exhibition of cinema films in which the machine was seen to rise without displacing chocks placed in front of the wheels Combined with its already proved ability of alighting with a practically negligible run, this makes it possible to visualise aircraft of this type operating from aerodromes of much smaller area, and less carefully kept surface, than hitherto Sea going operations, either from rough water or ship decks, are also facilitated by the absence of the need of horizontal run

THE combination of vertical lift followed by horizontal flight at the desired instant is attained by altering the pitch angle of the horizontal rotating lifting surfaces of the autogiro. These are set at the angle of no lift while the rotor is speeded up by a torque applied from the engine When the speed of rotation is considerably greater than that necessary for normal horizontal flight, the rotating mechanism is declutched, and simultaneously the angle of the surfaces is set to that for high lift Thus a lift in excess of the weight of the machine is created, and it rises When this impulse is expended, the machine would normally begin to descend, but in the meantime the full engine power has been changed back to the normal airscrew, and a thrust sufficient for horizontal flight is operating. This takes charge and the machine continues in horizontal or normal climbing flight at the will of the pilot The machine appears to leap only three or four feet in the films shown. Señor Cierva suggests that while jumps of the order of 60–100 ft are theoretically possible without needing prohibitive accelerations, an initial height of about 20 ft is all that practical considerations demand.

Television

THE recent publication of the report of the Postmaster-General's Committee on Television has aroused considerable interest in this subject not only among those technically interested in radio communication and broadcasting, but also among the general public, who now definitely envisage the prospect of being able to 'look' as well as 'listen' This interest has naturally given rise to a demand for literature, both technical and popular, on the subject. During the past year or so, however, progress in the technique of television at both the transmitting and receiving end has been so rapid that most of the books at

present available are useful only in explaining the fundamental principles of television or of illustrating the historical development of the subject, which dates back some sixty years With the object of temporarily filling this gap in the literature, the issue of the *Wireless World* of March 8 incorporated as a supplement a "Television Guide", comprising a 30-page booklet giving a simple explanation of the subject adequately illustrated by diagrams and photographs This guide assumes a knowledge of electricity and the principles of radio communication on the part of the reader, the principles involved in television are clearly explained, together with the use and limitations of mechanical scanning systems The manner in which the cathode ray oscillograph tube has been introduced into the art is described, with the resulting accelerated progress towards high definition television The most recent developments of picture transmission technique are dealt with, including Zworykin's iconoscope and Farnsworth's image dissector as alternative scanning systems, and the use of the intermediate cinematograph film for the broadcasting of current events The trend of this supplement to the *Wireless World* is definitely to explain the principles of the subject to the future owner of a television receiver, and as such, it may be said to form a useful appendix to the report of the Postmaster General's Committee

Safe Passing Speeds for Motor-Cars

EVERY driver of a motor-car who desires to pass another car going in the same direction has to consider the problem of whether it is possible or not Apart from the question of whether there is another car coming round the bend of the road in the opposite direction, he has to consider whether there is sufficient clear space ahead According to a Science Service message, Dr H C Dickinson, of the U S Bureau of Standards, has completed tests to find out how much clear space is necessary Assuming a speed limit of 45 miles an hour and that cars travelling 50 miles an hour are tolerated, he finds that a distance of 900 ft is required for safe clearance The time required to pass on a level road depends only on their relative speed of five miles an hour, and is nearly six seconds If the vehicle ahead is moving at 20 miles an hour the distance required is 650 ft, 200 ft. being required for the actual passing and 450 ft being the necessary allowance for a car approaching at 50 miles an hour The Highway Research Board of the U.S National Research Council points out that, considering the number of roads in the country where clear stretches of 900 ft are rare, there is often a serious risk when passing another car at high speed In mountainous country, winding and hilly roads would come under this category Dr Dickinson's figures apply to a car passing only one car ahead, when long lines of cars 'pile up' on the road, greater distances are required for safe passing.

Library of the University of the Witwatersrand

THE University of the Witwatersrand was the scene of a disastrous fire three years ago, when the greater part of its library, including the Gubbins and the Hoernle anthropological collections, was destroyed. Appeals for help led to a very substantial measure of replacement, gratefully acknowledged by the University in a letter to the Appeal Committee in London, which has now issued its final report In this, the chairman, Sir Frank Heath, observes that, while it is impossible to mention individually all the contributors, including learned, technical and scientific societies in England and America, universities and colleges throughout the British Isles and Canada, industrial firms, industrial research associations, British Government departments and the leading missionary societies having stations in South Africa, very special thanks are due to the British Association, the London School of Economics and Imperial Chemical Industries, Ltd New College, Oxford, and the Imperial College of Science and Technology helped to defray expenses of collection, packing, transportation and insurance The Union Castle Steamship Co undertook the transport of books at a discount of 50 per cent on the ordinary freight charges, and the High Commissioner for the Union of South Africa lent an office rent free The Universities Bureau of the British Empire placed its council room at the disposal of the Committee for its meetings Besides books and manuscripts, a large quantity of pictures, coins, etc., was collected which will form the nucleus of a Johannesburg municipal museum Some 32,000 volumes in all were dispatched by the Committee

A Giant Tortoise

A FINE specimen of Porter's black tortoise (*Testudo nigrita*) has just been added to the Tortoise House of the Gardens of the Zoological Society of London This is one of several species attaining a relatively gigantic size, which, a hundred and fifty years ago, swarmed in the Galapagos Islands, the Mascarene Islands, the Aldabras and the Seychelles Then they attracted the attention of mariners, who forthwith began to visit these islands and carry away their victims by the boat load Exploitation of this kind, whether of tortoises or whales, inevitably ends in extermination On only a very few of these islands are any survivors to be found to day But it fortunately happened that many species were taken to other islands where they bred This was the case with the species which has just come to the Zoo For Capt Porter, on his voyage from the Galapagos, in 1813, distributed several young tortoises from his stock among the chiefs of the Fiji Islands Many of these escaped, and bred there The great size of these animals is shown by the fact that the shell of the various species ranged from three to six and a half feet along the curve Until its death, a few years ago, the largest living tortoise known was owned by Lord Rothschild This was a specimen of *Testudo daudini*, of the South Island of Aldabra, taken, with six others, in 1895 The length of the shell was 55 in, or 67½ in over the curve The total weight was 560 lb. But even this was a mere pigmy compared with the extinct fossil tortoise (*Colossochelys atlas*) from the Lower Pliocene of the Siwalik Hills, India, which had a shell eight feet in length

Leukon Synthetic Resin

A NEW synthetic resin known as 'Leukon' was exhibited in granular thermo-plastic moulding form at the British Industries Fair by Imperial Chemical Industries, Ltd The main physical properties of the material are stated to be as follows. density 1 2 at 20° C, impact strength 4 kgm cm (Charpy units), tensile strength up to 10,000 lb per sq in, cross breaking strength 80/85 lb cantilever, Young's modulus 227 tons per sq in The material flows before breakdown under high pressure As regards the chemical properties of the material, it is said to be insoluble in water, alcohol and aqueous media, to be unaffected by acids or alkalies up to concentrations of 40 per cent in the case of sulphuric acid and caustic soda at atmospheric temperature, and to be unaffected by many high boiling organic esters It is soluble in certain of its forms in a number of organic solvents, including acetone, chlorinated hydrocarbons and benzene The material machines easily, can be die-stamped at 120° 140°, has very good insulating properties and low thermal conductivity A property which is emphasised is the capacity of the material for colour, in transparent, translucent or opaque forms

The Prehistoric Society of East Anglia

AT the recent annual meeting of the Prehistoric Society of East Anglia, held at the Norwich Castle Museum, it was resolved that in future the title of the Society shall be "The Prehistoric Society" Dr J G D Clark, in proposing the change, directed attention to the fact that the Society is no longer predominantly East Anglian either in membership or scope of work, and emphasised the point that the recognition of the Prehistoric Society as the only society operating on a national basis exclusively in the sphere of prehistoric archæology will be a contribution towards the much-desired rationalisation of the subject in Great Britain The Prehistoric Society of East Anglia was founded in 1908 by the late Dr Allen Sturge and the late W G. Clark of Norwich From very small beginnings it has grown until the membership now approaches 400 and includes the leading prehistorians in this and many other countries Prof. L'Abbé Henri Breuil, the retiring president, is succeeded by Prof. V Gordon Childe, with Mr M. C. Burkitt as vice-president, Dr J. G D. Clark as editor and Mr G Maynard, curator of the Ipswich Museum, as honorary secretary

The Philosophy of Sir James Jeans

IN the December number of *Adult Education*, Prof. L Susan Stebbing subjects Sir James Jeans's recent presidential address to the British Association to searching criticism. She complains that he has rated the intelligence of his hearers and readers too low by presenting them with contradictory statements concerning Nature, space and time, and knowledge. Some of the questions raised were referred to in our leading article on the address which was published in NATURE of September 8 last, but Prof. Stebbing makes no attempt to penetrate to the vital ideas which were expressed, however imperfectly, by Sir James Jeans; she contents herself with pointing out the imperfections As destructive criticism, the paper is of value, though, in the absence of counter-balancing constructive thought, it achieves less than its full potentialities Prof Stebbing fortunately does not make the common error of supposing that a single statement, by however distinguished a physicist, represents the unanimous view of 'physics' "The point to be maintained here," she says, "is that these cloudy speculations cannot properly be regarded as 'philosophical implications' of the new 'physics' " This goes far to justify what might otherwise be construed as a philosopher's attack on the philosophical tendencies of modern physics.

Biology, a new Journal

WITH the object of helping teachers of biology in different types of schools at home and abroad, the British Social Hygiene Council has launched a new journal, *Biology* It is hoped that the magazine will "serve as a medium for the interchange of ideas and information on practical and pioneer ventures in biology teaching" The scope of *Biology* is suggested by the articles in the first number They include one advocating microscope work, dissection and physiology of growth and development in elementary biology teaching, another describing the methods in use in African dependencies More general articles deal with plant communities and the school, the value of the micro-projector, biological activities out of school, and biology and general science in the First School Examination. The hesitation and delay in the introduction of biological teaching in schools throughout Great Britain is due largely to the indefiniteness of the subject's boundaries, and the lack of well organised graded courses of fairly definite content If *Biology* can lead to the development of such courses by pooling information, it will be performing great service to the science of life

Research on Causes of Blindness

MR WILLIAM H ROSS, chairman of the Distillers' Company, Ltd, who is himself totally blind, has recently given £40,000 to establish in Edinburgh an organisation "with the object of investigating the origin and causes of blindness, and utilising the results of such investigation towards its prevention and cure" The income from the money will be applied partly to research work on blindness, and partly to practical measures for its prevention and for the preservation of sight The chairman of the trustees is Dr Arthur H. H Sinclair, president of the Royal College of Surgeons of Edinburgh

New Australian Research Laboratories

Two new research laboratories are to be built for the Commonwealth Council for Scientific and Industrial Research, using money voted for relief of unemployment One, at a cost of £6,000, will replace an existing small building at the Council's viticultural research station near Mildura on the River Murray,

where investigations into problems of the dried grape fruits industry have been in progress for many years. The other will house the Forest Products Division, which hitherto has carried on in temporary quarters in Melbourne The new laboratory, to cost £25,000, will be in the midst of the city's timber yards, and this should mean decided increase in the practical effectiveness of the Division's work

Geographical Association

THE Spring Conference of the Geographical Association will be held at University College, Nottingham, on April 26–29 The meeting will include, in addition to several lectures and discussions, a long excursion to Southwell and Ollerton and visits to the tobacco factory of Messrs J Player and Sons, the hosiery factory of Messrs J B Lewis and Sons, and Messrs Boots new chemical factory Members will be accommodated as far as possible in the Hugh Stewart Hall of Residence Applications for accommodation and attendance at excursions should be made, before April 6, to Mr N V Scarfe, University College, University Park, Nottingham

Astronomical Exhibition in Paris

AT the next General Assembly of the International Astronomical Union, to be held at Paris on July 10–17, the French National Committee of Astronomy is arranging an exhibition of astronomical documents and apparatus, to exhibit the principles and the details of application of the methods of observation employed The examination of actual instruments shows better than any description how they are applied, while original negatives or positives on glass will enable the quality of the results obtained to be judged The exhibition will enable astronomers to examine the documents serving as the foundation of the astronomical discoveries of the present century It is particularly hoped that auxiliary apparatus and accessory contrivances of all kinds will be exhibited by observatories and instrument makers such instruments are micrometers, chronographs, photometers, spectrographs, driving motors, observing sheds and seats, abacuses, numerical tables and calculating machines Inquiries can be addressed to M le Comte de la Baume Pluvinel or to Prof C Fabry at the Paris Observatory

Sixth International Congress for Scientific Management

THE Sixth International Congress for Scientific Management, the first congress of its kind to be held in Great Britain, will take place on July 15 20 and will be opened by its patron, the Prince of Wales It will discuss commercial, agricultural and domestic problems and how far the adoption of the most scientific principles of management has facilitated their solution. Some three hundred chairmen, managing directors and professional and scientific men have so far enrolled, and the standard of the papers received from all parts of the world is most encouraging The organisation of the Congress is in the hands of a Council convened by the Federation of British Industries. Subjects to be discussed include: manufacturing, distribution, development, agricultural, educational and training, and domestic There is every indication that a really important gathering will take place H M Government is to invite members to a reception, and the Lord Mayor and Corporation will receive them in the Guildhall A series of visits to factories and institutions will take place in the week following the Congress Invitations to the Congress containing membership forms and full details may be obtained from the Secretary, 21 Tothill Street, London, S W 1

Catalogue of Microscopes and Accessories

WE have received from Messrs W Watson and Sons, Ltd, the new edition of their catalogue of microscopes and accessories (Parts 1 and 2) The pages devoted to principles of construction on the optical bench system, now applied to all Messrs Watson's microscopes, are of particular interest, and other constructional details in these pages are also noteworthy as evidence of the care devoted to the attainment of rigidity and accuracy Attention may also be directed to the description of the dark ground condenser which can be made with working distances up to 4 mm and to the low power binocular dissecting microscope, strong in build and with two pairs of objectives mounted on a double nosepiece so arranged that the pair not in use is turned into a protected position A considerable range of lamps for various microscopic purposes includes the Greenough lamp, which rests on the table beneath the microscope stage in place of the mirror and gives an evenly illuminated field, provision being made for centring the filament

Announcements

SIR JOHN AMBROSE FLEMING has been awarded the Kelvin Medal for 1935 of the Institution of Civil Engineers in recognition of his services to electrical science and particularly of his invention of the thermionic valve The Kelvin Gold Medal is awarded triennially as a mark of distinction in engineering work or investigation of the kinds with which Lord Kelvin was especially identified

AT the meeting of the Australian National Research Council at Melbourne in January, the first award of the Lyle Medal was made, the recipient being Prof J. R Wilton, Elder professor of mathematics in the University of Adelaide, for his work in mathematics This medal is to be awarded, at intervals of two years, to workers in Australia for such researches in mathematics or physics as may appear to the Council most deserving of such honour, the period covered by those researches being the five years preceding each award

THE services of Prof R. H. Dastur, professor of botany at the Royal Institute of Science, Bombay, have been secured on loan from the Bombay Government by the Government of the Punjab for the investigation of the cotton crop His address for some years, therefore, will be the Cotton Research Laboratory, Lyallpur, Punjab

THE Congress of the German Röntgen Society will be held in Berlin on April 28–30 under the presidency of Prof W. Baensch, from whom further information can be obtained at his address, Liebigstrasse 20a, Leipzig

A DISCUSSION on the "Origin and Relationships of the British Flora", to be opened by Prof A C Seward, has been arranged by the Royal Society for the morning and afternoon of March 28. Other speakers will include Mrs E M Reid, Prof P G H Boswell, Miss M E J Chandler, Dr H Godwin, Dr A J Wilmot, Prof E J Salisbury, Dr G Einar du Rietz, Mr H. Davey, Prof O T Jones, Dr R L Praeger, Dr K Sandford, Dr G C Simpson, Mr J B Simpson, Dr W B Wright

AT the annual general meeting of the Microchemical Club held on March 16 at the London School of Hygiene and Tropical Medicine the following officers were elected for 1935–36 *Hon Treasurer and Librarian*, Dr L H N Cooper, Marine Biological Laboratory, Plymouth, *Hon Secretary*, Dr S J Folley, National Institute for Research in Dairying, Shinfield, Reading Vacancies on the committee were filled by the election of Miss I H Hadfield and Dr. J R P O'Brien

THE International Association for the Prevention of Blindness will hold a meeting at the Royal Society of Medicine, 1 Wimpole Street, W 1, on April 5, during the Congress of the Ophthalmological Society of the United Kingdom The agenda are as follows (1) address by Prof de Lapersonne, president of the Association, (2) proposed international classification of the causes of blindness, by Prof van Duyse, of Ghent, (3) hereditary diseases of the eyes ending in blindness and their social consequences, by Prof Franceschetti, of Geneva

A SYMPOSIUM on the "Welding of Iron and Steel" will be held at the Institution of Civil Engineers, Great George Street, Westminster, S W 1, on May 2–3, under the auspices of the Iron and Steel Institute, in co-operation with the principal engineering and metallurgical societies of Great Britain The symposium will be divided into four groups, namely (1) present-day practice and problems of welding in the engineering industries, (2) welding practice and technique, including welding apparatus, (3) the metallurgy of welding, (4) specification, inspection, testing and safety aspects of welding Further information can be obtained from the Secretary, Iron and Steel Institute, 28 Victoria Street, London, S W 1

AN animal welfare society has just been formed in the Otani University, Kyoto, Japan, to be affiliated to the University of London Animal Welfare Society Prof Beatrice Susuki, professor of agricultural and forest chemistry, is leader and secretary Communications addressed to the new society will be received and forwarded by the University of London Animal Welfare Society, 68 Torrington Square, London, W C.1

THE Institute of Public Health of the University of Budapest, the sixtieth anniversary of which is to be celebrated this year, is the first institute of the kind to have been founded In 1882, public health became a compulsory subject in the Budapest faculty of medicine and in 1893 in the faculty of pharmacy The first director of the institute, Josef Fodor, who was also the founder of the Hungarian Society of Public Health, was a savant of world-wide reputation, and an excellent organiser, thanks to whose efforts the medical supervision of schools became generalised throughout western and southern Europe

WE have received from the Association of British Chemical Manufacturers, 166 Piccadilly, London, W 1, a copy of "British Chemicals, 1935" (Pp 459, bound in cloth) This is printed in English, French, German, Italian, Portuguese and Spanish, and gives the names of British manufacturers of classified products, a list of proprietary and trade names of materials, with their manufacturers, and indexes in the various languages The volume is published gratis, but is obtainable only on direct application to the Association by genuine purchasers of chemicals

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A temporary engineering assistant for the Directorate of Works in the War Office— The Under Secretary of State (C 5), The War Office, London, S W 1 (March 28) A chemist for rubber research (Malaya and Ceylon)— The Secretary, London Advisory Committee for Rubber Research (Malaya and Ceylon), Imperial Institute, London, S W 7 (March 28) A principal of the East Ham Technical College— The Secretary for Education, Education Office, Town Hall, East Ham, E 6 (March 30) Two junior assistant bacteriologists in the City Bacteriologist's Department, Liverpool—Town Clerk Municipal Offices, Dale Street, Liverpool, 2 (April 2) An assistant agricultural officer to the Kent County Council—The Chief Agricultural Officer, Brunswick House, Buckland Hill, Maidstone (April 4) A principal of the Northern Counties' Training College of Cookery and Domestic Science, Newcastle-upon-Tyne— The Secretary, 4 Royal Arcade, Newcastle upon-Tyne (April 8) An assistant keeper (second class) on the Higher Technical Staff of the Library of the Science Museum — The Director, Science Museum, South Kensington, S W 7 (April 13) A research worker in cancer—The Research Director, North of England Cancer Campaign, 14 Ellison Place, Newcastle-upon-Tyne (April 14) A demonstrator in organic chemistry at Bedford College for Women, Regent's Park, N W 1 —The Secretary (April 27) A chemist for the Main Drainage Department of the Ministry of Public Works, Egypt —The Chief Inspecting Engineer, Egyptian Government, 41 Tothill Street, London, S.W.1. A principal of University College, Nottingham—Alderman E Huntsman, 1 Bridlesmith Gate, Nottingham

ERRATUM. In the list of members of council of the National Institute of Sciences of India, printed in NATURE of March 16 (p 442), for "Dr. Baini Prasad" read "Dr Baini Prashad"

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 475.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Radioactivity of some Rarer Elements produced by Neutron Bombardment

EXPERIMENTS on the Fermi effect with some rarer elements have given the results summarised below. The neutrons were obtained from sources of radon, in quantities up to 100 millicuries, sealed in small glass tubes with powdered beryllium, and the radioactivity produced was measured with a Geiger-Muller counter which had been carefully calibrated with weighed amounts of uranium oxide. To utilise the enhanced activity produced by surrounding source and specimen with hydrogen compounds[1] most of the irradiations were carried out in a cavity in the middle of a large block of paraffin wax. The main results obtained are collected in the following table.

Element	Half life	Relative intensity
Silver	2·33 min.*	1
Iodine	25 min.*	0·7
Europium	9·2 hr. ± 0·1	19
Terbium	3·9 hr. ± 0·1	0·5
Erbium	2·9 hr. ± 0·1	3
Ytterbium (? Lutecium)	2·5 hr.	0·6
Germanium	c. 2 hr.	0·1

* Quoted from reference 2.

The relative intensities give a rough comparison of the activities produced per gram atom when irradiated in the wax block in a fixed position for a time long compared with the half life. Measurements on silver (2·33 min. activity) and iodine were also made to serve as standards.

Europium, terbium and gadolinium were kindly supplied as very pure oxides by Dr. J. K. Marsh. Europium shows a remarkably high activity compared with that of silver. Since the 20 sec. period of silver gives an intensity about four times that of the longer period, europium gives about four times the total activity of both periods of silver. The 'water effect' for europium was roughly determined and the activity was found to be increased forty times by irradiating the specimen in the wax block. The β-ray spectrum is now under investigation in the Physics Department of this College; the maximum energy is approximately $2 \cdot 0 \times 10^6$ e.v. In addition, γ-rays have been detected which are little absorbed by 4 mm. of lead.

A specimen of pure white gadolinium oxide (Gd_2O_3) which had been freed from europium and terbium[3] gave no detectable activity with the sources used. The activity with a half life of 8 hours reported by Fermi and his co-workers[2] may possibly be due to the presence of a small amount of europium, which is not easily separated except by the method of electrolytic reduction. The terbia used in these experiments had been carefully purified for atomic weight determinations[3].

Specimens of erbia and ytterbia originally supplied by Merck were kindly lent by Prof. J. F. Spencer. In addition to the strong activity with a half life of 2·9 hours, erbia gave a much weaker activity with a period of *c.* 30 hours. As, however, the specimen used may contain other rare earths, this period cannot definitely be ascribed to erbium. The ytterbia contained lutecium, so that the activity observed may be due to this element. It is hoped shortly to settle this point by examining specimens of these elements which have been separated by electrolytic reduction.

A specimen of pure scandia from Messrs. Adam Hilger, Ltd., which had been tested spectroscopically and was at least 99 per cent pure, gave no detectable activity when irradiated for 15 hours with 100 millicuries. Another specimen kindly lent by Prof. G. T. Morgan also gave no activity. The activity with a period of 16 hours reported by Hevesy[4] must presumably have been obtained with much stronger sources of neutrons.

I am much indebted to Prof. P. M. S. Blackett for his encouragement and advice whilst this work was in progress.

S. SUGDEN.

Curare

IN 1931 Hartridge and West[1] noted a rigidity-removing ('lissive') action of curare in experimental parathyroid tetany in dogs. The application of the drug to diseases involving muscular rigidity in man was undertaken by West in a wide series of cases[2]. As it was observed quite early in the investigations that the 'lissive' action was apparently only present in certain samples of curare and might be due to some constituent other than the 'curarines' to which the classical action of curare is due, a broad chemical survey of the much neglected field of the curares was undertaken by the writer in close co-operation on the pharmacological side with Dr. Ranyard West.

Through the valuable co-operation of the Curator of Forests, British Guiana, we have been able to examine a number of *Strychnos* species, kindly identified botanically by the Kew authorities, for pharmacologically active alkaloids. The species examined, their numbers in the Forest Department Records[3], and their approximate relative total alkaloidal contents are shown in the following table.

Species	Rec. No.	Alkaloid Content.
Strychnos Erichsonii	2284	+ + + +
" *toxifera*	2278, 2285	+ + +
" *Melinoniana*	2260, 2279, 2286; 2303	+ +
" *diaboli*	2295	+ +
" *diaboli ?*	2270	+
" *Mitscherlichii*	2261	0
Guettarda acreana	2317	+ + + +

Of these *Strychnos* species one only, *St. toxifera*, contains an amorphous quaternary alkaloid, to the extent of 0·2 per cent, indistinguishable chemically and pharmacologically from the paralysing principle curarine isolated from calabash or gourd curare from

various native sources Curarine from either source is readily isolated after suitable preliminary treatment, by precipitation with mercuric chloride, further purification being effected through the sparingly soluble amorphous iodide This is the first occasion on which curarine has been isolated from *St toxifera* bark of certain identity, and it confirms Robert Schomburgk's discovery of *St toxifera* as the source of the main active ingredient of the curare of the Macusi Indians *Guettarda acreana* is a reputed ingredient of native curare, but although rich in alkaloids, it does not contain a paralysing principle

Through the kindness of the Department of Ceramics of the British Museum and of Mr T E Wallis, curator of the Museum Department of the Pharmaceutical Society, we have been able to examine native preparations of tubocurare, put up in bamboo tubes and quite distinct from calabash curare as was emphasised by Boehm The other soluble crystalline alkaloid *l* curine isolated by Boehm from tubocurare has already been shown by Späth, Leithe and Ladeck to be the optical enantiomorph of *d* bebeerine (α chondodendrine), an alkaloid found in *Radix Pareirae bravae* (Chondodendron spp) by Scholtz The accompanying quaternary alkaloid tubocurarine obtained in an amorphous state by Boehm[4] has now been crystallised for the first time and has a paralysing activity on the frog only slightly less than that of curarine from *St. toxifera* Tubocurarine is dextro-rotatory and has the empirical formula $C_{19}H_{22}O_4NCl$, which if doubled would make the salt isomeric with bebeerine methochloride. The double structure is supported by the results of *o* methylation Although *d*-tubocurarine chloride and *d* bebeerine methochloride are closely similar in general properties, they are not identical; and *d*-bebeerine methochloride has a paralysing activity on the frog considerably less than that of *d* tubocurarine chloride

The nature of the isomerism between *d* tubocurarine methochloride and *d*-bebeerine methochloride is under investigation, their *o*-methyl derivatives are different, but it is suggested that both will be represented eventually as being built up from two norcoclaurine units[5] HAROLD KING

Flame Temperatures

WE have expressed the view[1] that flame temperatures determined by the sodium line reversal method are in general far greater than the true flame temperatures (mean molecular translational energy), but considerable criticism has been received which suggests a firmly held opinion that the sodium method measures true flame temperatures—at least approximately The following facts are put forward in support of our view

The sodium method and the platinum resistance method (a 0 0005 in. platinum rhodium wire) yield very nearly (and almost exceptionally) the same temperatures during the combustion of carbon monoxide – air mixtures in the neighbourhood of the 'correct' mixture But as the mixture strength is varied, the two methods yield temperatures which increasingly differ from one another until a 52 per cent mixture is reached, when the difference amounts to

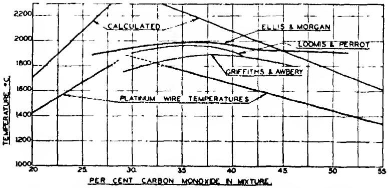

FIG 1 Flame temperatures in carbon monoxide - air mixtures The calculated temperatures are shown uncorrected for dissociation As the actual temperatures in the flame gases are less than 2,000° C, dissociation in them is small and a fairer perspective is obtained by comparing them with calculated temperatures uncorrected for dissociation

as much as 500° C The sodium temperatures as measured by Ellis and Morgan[2] (using a Smithell's separator supplied with perfectly mixed mixtures) remain roughly constant over this wide range of mixture strengths at rather more than 1,900° C (and qualitatively similar results were obtained in the sodium measurements of Loomis and Perrot and Griffiths and Awbery). The platinum wire temperatures, on the other hand, drop through this range of mixture strengths by more than 400° C, and this is much in accord with what would be expected from calculation

These results may be confirmed by an inspection of curves shown in Fig. 1 It will also be seen that for very over-rich carbon monoxide – air mixtures the sodium temperatures of Ellis and Morgan are much in excess even of the ideal temperatures calculated upon the basis of complete combustion and no radiation loss (some 200° C in excess in the case of the 52 per cent mixture) An examination of the large numbers of sodium measurements made by Jones, Lewis and Seaman[3] in various hydrocarbon – air flames shows that they too are frequently much greater than the calculated temperatures—particularly in the case of very over-rich mixtures and sometimes in the case of weak mixtures

In general, then, sodium flame temperatures should not be taken at their face value as indications of true flame temperatures The error in doing so may amount to hundreds of degrees centigrade. Of course the sodium temperatures must have some significance, and a clue to this may possibly be found in the fact that most of the sodium measurements on record in scientific literature, when examined over a wide range, suggest a tendency towards independence both of the nature of the combustible gas and of the mixture strength; in any event they do not

vary nearly so much as the calculated temperatures

Our platinum temperatures for all gases so far examined vary with the mixture strengths very much at the same rate as the calculated temperatures, but they are many hundreds of degrees below them[4] It has been suggested that this is because they require a very large correction for radiation loss We have given many reasons for the view that our measurements (which we have always given uncorrected for radiation loss) do not require a correction of more than about 40° C even at the highest temperatures, and indeed if they did they would be much above the sodium temperatures in the neighbourhood of the 'correct' carbon monoxide air mixtures (see Fig 1)

Our measurements were made during the pre pressure period in gaseous explosions, and we took continuous records for a considerable time after the flame front had passed over the platinum wire but there were no signs of increasing temperature Indeed the temperature remained remarkably steady

It was mainly for these reasons that we felt justified in postulating that flame gases hold a long lived latent energy, which in flames burning at atmospheric pressure seems never to be less than about 15 per cent of the heat of combustion, and in the case of carbon monoxide flames is of the order of 20 per cent

Stokes's Formula in Geodesy

IN NATURE of February 20, 1932, a letter appeared from Mr B L Gulatee under the above heading This was responded to by Mr Walter D Lambert in the issue for June 4, 1932

Mr. Gulatee showed me his letter before he sent it off, we discussed it together, and on the whole I agreed with it; but during the past year I have given much attention to the application of Stokes's method to the determination of the earth's figure, and a paper on the subject has just been communicated to the Royal Society.

I am now convinced that, while Mr Gulatee's letter is generally correct in the statements made it gives a wrong impression of the case Mr Gulatee said, "I believe it will never be possible to use it [Stokes's method] for getting absolute elevations" My recent studies have convinced me that it will be possible to do so.

Mr Gulatee gave some figures showing a particular case as example in which an error of 0 01 gal in 'g' would lead to an error of 40 ft in geoidal elevation, and he added that "A systematic error of 0 01 in zones from 40°–100° and of − 0·01 in zones from 130°–170° would vitiate the results hopelessly", which is very true Systematic errors are very much to be guarded against and it is essential that all possible precautions be taken to avoid them. However, a systematic error of 0·01 over the whole globe would lead to zero error of geoidal elevation; and it is artificial to suppose that systematic error should prevail over one half (nearly) of the globe and then reverse its sign for the other half, as suggested in the quoted passage. When a considerable region of the earth, such as 100,000 square miles, is to be represented by a single gravity determination, it is no doubt true that the observed anomaly will deviate from the mean value for the area, but *not* systematically The deviation, which may be called the 'representative error', is mainly of the nature of an accidental error, due to irregularities in the earth's crustal density, and so the combined effect of such errors in each of some 2,000 elementary areas of quadrature should be very different from what was suggested by Mr Gulatee

In my paper, alluded to above, I have gone carefully into this matter I find that, with 1,700 stations evenly spaced over the earth's surface, combined with 100 stations suitably distributed locally, the probable error of geoidal elevation at a point will be $\pm$ 34 ft, while the probable error of tilt, found from a derived formula, will be $\pm$ 0 35 in

It is to be noted that 34 ft is only $1\,6 \times 10^{-6}$ of the earth's mean radius, and such precision is of the same order as though smaller than, the lowest estimates of probable error of the earth's mean radius For fixing the elevation of the origin of a large survey, which is a practical requirement, the accuracy is ample in relation to the standard of accuracy of the survey, and there is every justification for making the necessary gravity determinations to enable the calculations of geoidal rise and tilt to be carried out

Three-fold Magneto-ionic Splitting of the Radio Echoes reflected from the Ionosphere

THE phenomenon of reflection of radio waves from the ionosphere and the observed echo patterns has received satisfactory explanation from the magneto-ionic theory, first put forward by Appleton[1]

It is well known that a dispersion formula can be easily obtained from the generalisation of Lorentz's treatment of the problem of the propagation of the electromagnetic wave in a magnetic field For vertical propagation, when damping is negligible, it has been shown that

$$\mu^2 = 1 + \frac{2}{-2\alpha - \frac{\gamma_T^2}{1+\alpha} \pm \sqrt{\frac{\gamma_T^4}{(1+\alpha)^2} + 4\gamma_L^2}} \quad . \quad (1)$$

where

$$\alpha = -\frac{n^2 m}{N e^2} - 1, \quad \gamma_T = \frac{n h_z}{eNc} \text{ and } \gamma_L = \frac{n h_x}{eNc}$$

Reflection occurs when μ is equal to zero. From formula (1) we can plot a dispersion curve for various values of N, the number of electrons in a unit volume It can then be shown that we get μ equal to zero for three different values of N (N_1, N_2, N_3) obtained from the conditions given below

$$\left.\begin{array}{ll} 1+\alpha = -(\gamma_T^2+\gamma_L^2)^{\frac{1}{2}} \quad . & (a) \\ 1+\alpha = 0 \quad . \quad\quad . \; . & (b) \\ 1+\alpha = +(\gamma_T^2+\gamma_L^2) & (c) \end{array}\right\} \quad . \quad (2)$$

From these conditions it appears that there will be

three different heights corresponding to the above three values of N from which we can get reflections. But usually only a doublet is observed corresponding to conditions (a) and (b) of formula (2) Corresponding to (a) we get an extraordinary ray (shorter delay component) and corresponding to (b) we get an ordinary ray (the longer delay component) Reflections corresponding to (c) or N_3 (which is the highest concentration of electrons for which μ is again zero) are not usually observed, since the amplitude of the disturbance when it reaches the greatest height is very small, or even if it is reflected with sufficient amplitude from these heights the amplitude falls during its passage through the lower layer (See Mary Taylor[2] who considers this possibility)

As already reported in NATURE[3], a systematic investigation of the heights of the ionosphere is being carried out in this laboratory, and on several occasions different observers[4, 5] have independently noticed the appearance of a very close triplet set of the first reflected echo, two of these can be easily identified with those corresponding to N_1 (2,a) and N_2 (2,b), but the third can only be identified with N_3 (condition 2,c) The most favourable time for the occurrence of the triplet seems to be after sunset, when the first echo from the F-layer just begins to resolve into the ordinary and extraordinary ray The triplets occur rather irregularly and have not been found to exist for more than a minute On most favourable occasions when the measurement could be taken from visual observations, the separation of the components corresponded to an equivalent height of about 15 km

Absorption of Cosmic Rays

THE Klein-Nishina formula, which is based on the scattering and absorption of X- and γ-radiation by extra-nuclear electrons, has been widely used in the calculation of the absorption coefficients of high-frequency quanta. But recent experimental work and theoretical deductions have shown that this formula is not applicable to the absorption of γ radiation of energy greater than $1 \cdot 0 \times 10^6$ e v, since for higher energies there is additional absorption due, in the main, to interactions between the radiation and atomic nuclei, these interactions giving rise to electron pairs This nuclear absorption, which becomes of greater importance as the energy of the quanta increases, and is probably the predominant type of absorption which would occur with any ultra γ-radiation arising from actions such as the condensation or annihilation of protons and electrons in space, is not accounted for by the Klein-Nishina formula The latter cannot, therefore, be directly applied to the cosmic ray problem as has been previously assumed, and the wave-lengths of supposed photon components calculated by means of this formula must be inaccurate, since the formula does not take into account the nuclear absorption.

Even assuming that the primary rays are photons, the agreement which has been obtained between the absorption coefficients calculated by assuming some hypothesis as to the process giving rise to the quanta, and the experimentally observed coefficients, is fortuitous, since nuclear absorption is neglected by the Klein-Nishina formula Thus, before any postulation as to the origin of the rays which utilises agreement between calculated and observed absorption coefficients of ultra γ radiation can be accepted, a theory of absorption which takes account of nuclear interactions must be developed

Random Distribution of Parasite Progeny

RECENT work by Salt[1] led him to question the validity of the hypothesis of the random distribution of progeny by parasites In this connexion, experiments at Farnham House Laboratory with *Schedius kuvanæ*, a chalcid egg-parasite of the gipsy moth (*Porthetria dispar*), will be of interest Although no figures are given here, those obtained in the experiments were such as to leave no doubt as to their significance

Subject to controlled environmental conditions, and given a sample of host eggs all equally exposed to attack, the female almost invariably parasitises each available host with a single egg. If no healthy (unparasitised) hosts are present, the rate of laying (per diem) is approximately halved, that is, she tends to retain her eggs rather than deposit them in parasitised hosts There is considerable individual variation in this ability to refrain from ovipositing in parasitised hosts—a feature which was also indicated in the table of Salt's work on *Trichogramma evanescens*

The discriminating faculty is not due to memory, and seems to be of a qualitative rather than a quantitative nature. When a series of *Porthetria* eggs, containing respectively 0, 1, 2, 3 and 4 eggs deposited by a given female, are exposed to another female for a given time, at least 80 per cent of the progeny are placed in the hosts that contained no eggs when first offered to the female, these often being superparasitised with three or four eggs This peculiarity of laying the great majority of additional eggs in hosts which a given female had herself parasitised in the original instance, in preference to hosts parasitised by other females, has been noticed in numerous cases where superparasitism was enforced by the experimenter.

The selective faculty is of a surprisingly high order, enabling the insect to choose the best of available host material. Thus, given a choice between—

(1) dead and alive gipsy moth eggs, she selects chiefly live eggs ;

(2) dead healthy eggs and dead eggs, each containing a single dead parasite, she selects the healthy host ;

(3) dead healthy eggs and dead eggs, each containing a single live parasite, again the healthy eggs ,

(4) dead eggs each containing a single dead parasite and dead eggs containing a live parasite, she usually deposits in the former

It should be stated that the female *Schedius* deposits her egg in the host with a portion of the pedicel protruding through the gipsy-moth egg shell, this probably performing a respiratory function To eliminate this as a means of distinction between parasitised and unparasitised eggs, all pedicels were removed with a sharp scalpel before the experiments. These preliminary experiments suggest that the oviposition response in *Schedius* cannot be due to any simple stimulus It is hoped to investigate the conditions under which this selective faculty is impaired or destroyed.

Diet of Seals

THE recent illegal slaughter of grey seals in the supposed interests of the Cornish fishermen directs attention to the diet of seals On what do they usually feed ? On fish, as the fishermen and their friends assert, or on some of the other creatures which abound in the waters of the ocean ?

Obviously the diet of seals, like that of whales, can be ascertained only by opening their stomachs and examining their contents In the case of the arctic and antarctic seals this has been done to a considerable extent

Nansen[1], R Brown[2], Kumlein[3], Malmgren[4] and Chapman Spencer[5] all testify to the extent to which the arctic seals feed on creatures other than fish—squid, crustaceans and shellfish—and, in the case of the antarctic seals, the evidence of E A Wilson[6] and Matthews[7] is equally strong

As to the diet of the grey seal, there seems to be very little scientific evidence beyond that which is contained in Mr. Steven's report[8] Unfortunately, Mr. Steven was only able to examine the stomach contents of three seals; there were fish remains in two, and a cuttle-fish beak in a third The examination by him of a greater number of stomachs might have led to the discovery of more remains other than those of fish, that is, those of crustaceans and shell-fish, and might have still further weakened the case against the grey seal.

Until the matter is more fully investigated, the destruction of grey seals on the plea that they destroy large quantities of food-fish does not seem to be justified.

Red 'Water-Bloom' in British Columbia Waters

IN NATURE of September 22, 1934, there is a communication from Mr T. John Hart describing the occurrence of a red 'water-bloom' caused by *Mesodinium* in South African seas It may be of interest to record an occurrence of blood-red water at Nanaimo, British Columbia, during the week of April 28, 1933 The water in a channel immediately north of the harbour was coloured crimson red in great patches Examination of a sample of the water revealed a pure culture of a ciliate, identified by Mr G H Wailes as *Mesodinium rubrum*, Lohmann

About this time oysters in Ladysmith Harbour, fifteen miles south of Nanaimo, were reported to contain red 'worms' Investigation disclosed the fact that the crystalline styles were coated with a red colouring matter, evidently as a result of feeding upon *Mesodinium* Examination of the styles of local clams showed a similar condition

The appearance of this 'bloom' of *Mesodinium* followed a period of a couple of weeks of bright, sunny, calm weather No discoloration was observed in 1934

Magnetic Measurement of Ionic Deformations in Crystals

DURING the past few years, it has been shown that the diamagnetic susceptibilities of ions in crystals are approximately additive, and their values are in fairly close agreement with values calculated theoretically from the wave mechanical structures of free ions[1] Attempts to interpret the experimental results in more detail have been handicapped by a lack of essential data, for although results are now available for many substances, some have been obtained for solutions and others for crystals, and the two are not directly comparable. With the view of obtaining more precise information for a particular group of crystals, we have studied the susceptibilities of the alkaline halides, using a method of measurement previously described[2]

We have been specially interested to see how closely the additivity principle holds in this group of crystals, and we find that in general it holds to within 1 per cent The results for the rubidium halides are typical

Salt	Diamagnetic Susceptibilities $\chi \times 10^6$ (1) Obs	(2) Calc	$\Delta\chi$, (1)–(2)
RbF	31·9	31·4	−0·5
RbCl	46·4	46·2	−0·2
RbBr	56·4	56·5	0·1
RbI	72·2	72·6	0·4

The only important exceptions to the additivity rule are the chlorides, bromides and iodides of lithium and cæsium, for which the calculated values exceed the observed values by 1·6, 1·5 and 1·3 in the case of the lithium salts, and by 2·7, 2·4 and 3·1 in the case of the cæsium salts For the other halides upon which measurements have been made in the course of this work, the differences are of the order of 0·2–0·3.

Exceptional results might have been expected for the cæsium halides, since these crystals have a different structure from the other halides, all of

which have the rock-salt type of structure. A different explanation is suggested in interpreting the results for the lithium halides. These crystals are composed of the small Li^+ ion and the relatively large Cl^-, Br^- and I^- ions; the negative ions here approach more closely than in the other halides, and the greater electrostatic repulsions produce larger interatomic distances than would be expected from considerations of the 'sizes' which these ions have in the other halides[3]. The conclusion we draw is that the interatomic forces which thrust apart the negative ions in the lithium halides and result in a change of structure in the case of the cæsium halides produce deformations of the ions which *lower* their susceptibilities. We find that this conclusion holds good also for the ammonium halides, the chloride and bromide of which normally have the CsCl type of structure and show low values for their susceptibilities, while the iodide has the NaCl type of structure and gives a normal susceptibility.

A detailed account of this work will appear elsewhere.

Variation of the Carbon-Halogen Link Distances in Different Types of Organic Structure

THE improved electron diffraction method[1] of determining molecular structure in the vapour phase has brought to light the fact that the distance between a carbon and halogen atom depends on the character of the binding attaching the carbon atom to other atoms in the system. Hitherto, the magnitude of this distance has been regarded as constant. We have shown that the carbon-halogen distance is smaller in aromatic compounds than are the accepted values for the aliphatic series[2]. This suggested that an investigation of certain aliphatic, ethylenic and

	Aliphatic >C-Hal		Ethylenic =C<(Hal)(Hal)		Aromatic C-Hal	Acetylenic ≡C-Hal
Link	New	Old	New	Old	New	
C-Cl	1 76[7]	1 82[4,5]	1 74	1 82[7,6]	1 69	—
C-Br	1 93	2 05[4,5]	1 91	2·05[6]	1 88	1 84
C-I	2 12	2 28[4]	2 10	—	2 05	2·03
	CCl_4 CBr_4 CHI_3		*Trans* $C_2H_2Cl_2$ „ $C_2H_2Br_2$ „ $C_2H_2I_2$ C_2Cl_4 C_2Br_4 C_2I_4		C_6Cl_6 C_6Br_6 Sym $C_6H_3Br_3$ „ $C_6H_3I_3$ *p*- $C_6H_4Br_2$ *p*- $C_6H_4I_2$	Dibrom-acetylene Diiodo-acetylene

acetylenic compounds by electron diffraction might throw more light on this question.

The 'new' results are tabulated above, showing that the carbon-halogen link distances in angstroms decrease from left to right and are not constant, as the 'old' results would seem to indicate. The order of accuracy is ± 0 01 A. Below each column we give a list of the substances used for this work, the results of which will be published shortly in greater detail.

Dipole Moment of Acetonitrile

ALTHOUGH several determinations of the dipole moment of acetonitrile have been made, considerable uncertainty attached to the results since the values of different observers varied widely. The figures already published for this compound are as follows:

	μ	Temp.
Williams, *Z. physikal. Chem.*, **138**, 75; 1928	3 4 D	25° C.
Werner, *ibid.*, B, **4**, 371; 1929	3 11	20°
Eide and Hassel, *Tids. Kjemi*, **10**, 93; 1930	3 51	—
Hunter and Partington, *J.C.S.*, 2812; 1932	3 16	20°
Snoek, *Physikal. Z.*, **35**, 196; 1934	3 45	25°

In all cases the solvent was benzene.

We recently remeasured the moment of acetonitrile in connexion with some other work, shortly to be published, and have found a value $\mu = 3{\cdot}44 \pm 0{\cdot}02$ D at 20°. This figure is in excellent agreement with that obtained by Snoek.

The two lowest values quoted above were both found using acetonitrile which had been repeatedly fractionated with phosphorus pentoxide. This treatment would not remove traces of acetic acid formed by slight hydrolysis of the cyanide, and possibly the low values are in part due to this cause. It may be noted that the moment of acetic acid in solution is about 0·8 D (Wolf; *Physikal. Z.*, **31**, 227; 1930) although smaller values have been recorded.

In the present experiments, Kahlbaum's acetonitrile was purified by standing over caustic potash to remove any traces of acid, was then left in contact with calcium chloride for a week to remove any ammonia, and was finally dried with phosphorus pentoxide. It was twice fractionated over phosphorus pentoxide, and had a constant boiling point 81·6°C./760 mm.; d^{20}_{4} 0·7823; n^{20}_{D} 1·3438. Kahlbaum's benzene was used as solvent.

The dielectric constants have been measured on an improved form of the apparatus previously used by us, which we shall describe elsewhere.

The polarisations of acetonitrile are: $P_{\infty} = 262 \pm 1{\cdot}5$ c.c.; $P_E = 11{\cdot}1$ c.c.; $\mu = 3{\cdot}44 \pm 0{\cdot}02$ D.

Solid Carbon Dioxide

THE commercial and workshop value of solid carbon dioxide is fully described in a recent article in NATURE[1], there are, however, further interesting uses of this material to which it may be worth while to direct attention

(1) Diamonds and pearls may at once be distinguished from their counterfeits, inasmuch as the real substances emit a rattle or squeak when touched with solid carbon dioxide Similarly, a quartz lens may at once be distinguished from a glass one

(2) Metal bars and tuning forks of high pitch may be powerfully excited by touching them with the substance, and the overtones of low-pitched forks and bars may similarly be picked out—a fact of practical importance in the tuning of metal bars of musical instruments

(3) Brittle materials, of suitably high thermal conductivity, may also be set into vibration

These facts, and the manner of their discovery, were demonstrated before Section A at the York meeting of the British Association As no trustworthy account exists on the origin of these experimental researches, I should like to put on record the actual facts. The well-known fact that solid carbon dioxide will make a bicycle bell rattle was brought to my notice on July 11, 1932, by an itinerant vendor of ice-creams, and investigations were at once entered into, the results of which, together with an explanation of the phenomenon, have recently been published[2,3] Briefly, the loss of heat from the hotter to the colder body supplies the energy, and the efficacy of carbon dioxide is due to the fact that it sublimes, thereby producing considerable gas pressure.

I have recently noticed that solid carbon dioxide in the form of 'Drikold' can set soft metals into vibration in a manner impossible with a hammer

The accidental nature of the discovery and the mechanism of the phenomenon may well be compared and contrasted with that of Trevelyan's rocking bar

Points from Foregoing Letters

PROF S SUGDEN has investigated the radioactivity induced by neutron bombardment (Fermi effect) in the rarer elements europium, erbium, terbium, ytterbium, etc) He tabulates the relative intensity and half-life periods of the radioactive elements produced, comparing them with the intensity produced in silver and iodine in the same circumstances.

Curare and tubocurare—plant extracts employed by South American Indians as arrow poisons because of their paralysing properties—have been used medically to alleviate muscular rigidity in man Dr Harold King has investigated several species of *Strychnos* and other plants from which curare is said to be obtained Of these, *S toxifera* alone contains the active principle curarine, having paralysing properties Chemical examination of bamboo-tube curare (tubocurare)[1] yielded crystalline tubocurarine, which has properties similar to those of curarine, together with an allied substance *d* bebeerine, which is much less active

The temperature of flames as measured by the increased resistance of a platinum wire does not agree with that determined by the 'sodium line reversal' method (The spectral lines of sodium present in the flame seen against a background of a continuous spectrum of a tungsten filament, of known temperature, appear dark when the flame is cooler and bright when it is hotter than the filament) Prof W. T. David maintains that the 'sodium temperatures' are too high, as they do not agree with the calculated temperatures fo flames of carbon monoxide while the 'platinum temperatures' do The sodium temperatures show an unexpected constancy over a wide range of variations in the mixture strength and in the nature of the combustible material.

Stokes's formula shows how, from a knowledge of the variations in gravity at different known points of the earth's surface, one may calculate the shape of the earth's figure (geoid) Mr B L Gulatee suggested that minute systematic errors in the determination of g might completely vitiate the results Dr J de Graaff Hunter now calculates that if gravity determination were made at a large number of stations suitably distributed over the earth, Stokes's formula would give the 'absolute elevation' with a fair degree of accuracy.

According to theory, there should be three different heights in a given ionic layer (of the upper atmosphere) from which radio waves can be reflected, these correspond to certain values in electronic density. Only doublet echo patterns are, however, usually found Mr G R Toshniwal states that triplet radio echoes have been observed at Allahabad from the F layer—especially after sunset; the separation of the components indicates an equivalent height difference of about 15 km

Mr H J Walke points out that the Klein-Nishina formula by means of which the wave-lengths of γ-rays are calculated when their absorption coefficient is known neglects nuclear absorption It should not therefore be applied in the case of γ-rays of more than one million electron volts energy, such as those supposed to exist in cosmic rays, since such hard γ-rays can interact with atomic nuclei.

Mr D C Lloyd reports that experiments with the parasite wasp (*Schedius Kuvanae*) which deposits its eggs within those of the gypsy moth, show that the female *Schedius* possesses a selective faculty enabling it to pick the best available material as host.

Mr G W Brindley and Dr F. E Hoare have investigated the diamagnetic susceptibilities of the alkaline halides in order to test how nearly additive are the ionic susceptibilities in this group of crystals. They find that the additive rule holds to within about one per cent in all cases except CsCl, CsBr and CsI (which have different structures from the other halides), and LiCl, LiBr and LiI (where the negative ions are in unusually close proximity)

Research Items

Blood Groups and Physiognomy. Prof R Ruggles Gates has recently received from Dr L D Livingston the photographs of six out of eleven Eskimo of Pond Inlet (lat nearly 73° N) tested by him for blood-groups, who were regarded as "practically full-blooded Eskimo" The photographs are published in the March issue of *Man* On inspection by several anthropologists and laymen, two out of the six were selected as pure-blooded, while of the remainder one was singled out by one observer who had experience of Canadian Indians as having Indian blood The remaining three were regarded by all observers as having European blood This classification agrees with the blood groups The two individuals selected as pure Eskimo belong to the *O* group, the remainder to the *A* group In the instance of the individual showing Indian admixture, this must be explained as due to a remote white strain, which does not show in the features Otherwise the evidence of physiognomy agrees entirely with the evidence of the blood groups, as usually accepted for American aborigines The striking fact which emerges is that while the pure-blooded are *O*, those of mixed ancestry are all *A*. It is pointed out that a European who has the *A* group is more likely to be heterozygous than homozygous for *A* Any white man who is heterozygous for *A* would have an equal chance of transmitting to his offspring in a cross with an Eskimo the genes for European features combined with either blood group *A* or *O* One must conclude, therefore, that while crosses between a white father who was heterozygous for *A* and an Eskimo woman would in many cases be expected to produce a child of *O* blood-group combined with some European features, yet on the other hand the presence of *A* in the offspring can be taken as confirming the evidence from physiognomy that a cross has taken place

Mortality amongst Game Birds. The Hungarian partridge (*Perdix p perdix*) has been introduced into the Great Lakes region of the United States, and there it is better adapted to intensively farmed areas than the native game birds or the pheasant, with neither of which does it seem to compete Large numbers, amounting to more than 260,000 individuals, have been set free in the United States and Canada, mostly during the present century. In the course of a careful description of the standing and relationships of the Hungarian partridge in the Great Lakes region, Ralph E. Yeatter discusses the mortality at different stages. In the breeding seasons of 1930, 1931 and 1932, out of a total number of 143 nests observed, 32 per cent were successful, 68 per cent unsuccessful The causes of failure were mainly farming operations, which accounted for 46 per cent of the destruction, predators (26 per cent), desertion (16 per cent), while smaller losses were due to farm animals and hatching failures (Bull. 5, Univ. Michigan, School of Forestry and Conservation, Dec. 1934). In later life, careful counts of birds in definite localities were made during the year, and these again showed a very marked decrease in numbers, both during the winter period, when in one case there was an 11 per cent loss in the course of a month, and during late summer in young birds in their first few weeks Losses of adults appear to be gradual through autumn, winter and spring.

Aeroplane Dusting and Bees. According to Science Service (Washington, D C.), bees are often destroyed by poisonous dusts spread by aeroplanes as a means for combating insect pests The matter came up for discussion before the American Association of Economic Entomologists at a meeting held in Pittsburgh on December 27. One speaker maintained that such aeroplane dusting is responsible for the reduction of about one million colonies of the honey-bee in the United States during the past three decades The mischief, it is stated, is mainly caused by the drift of poisonous dust into the flowers where they are working Pollen-gathering bees themselves are unaffected owing to the fact that the pollen is stored on their legs and bodies, but the poisonous food is transferred to the hive, where it is fatal to the larvæ, thus inhibiting the increase of the colony at its source

Historical Investigation of Heterœcism. A study of the heterœcious fungus *Puccinia graminis* is now part of even an elementary course of biology, and it is difficult to conceive that there was a time when the link between its two hosts, barberry and wheat, had not been established Mr J Ramsbottom has published an interesting article (*Trans Brit Mycol Soc*, 19, Part 2, 128–138, January, 1935), which reveals the extensive observations made by L G Windt, on the connexion between the two hosts Windt was a "counsellour in the chamber of accounts of the Count De Lippe Schaumberg", and published his findings in a book "Der Berberitzenstrauch, ein Feind des Wintergetreides" ("The Barberry-bush an Enemy to Winter Corn"), 1806 The incidence of disease on wheat and rye when barberry bushes grow in the neighbourhood was established in different places and on numerous occasions Then wholesale eradication of the bushes was recommended, and sponsored by the Count. This measure was entirely successful, and the book closed with a summary of the available knowledge about the causal fungus. A passage, obviously written just before publication, acknowledges Sir Joseph Banks's demonstration that the æcidium fungus on barberry and the *Puccinia* on wheat were really stages of the same fungus

Cretaceous Mollusca of Japan. The Cretaceous Lamellibranchs and Gasteropods of the Miyako district of Honshû, Japan, have recently been described by T. Nagao (*J Fac Sci., Hokkaido Imp. Univ.*, 4, (2), 177–277; 1934). The Cretaceous deposits occur in six small areas along the eastern border of the Kitakama mountainland in north-eastern Japan, where they rest unconformably on Palæozoic or igneous rocks and consist mainly of sandstones with some layers of shale and conglomerate. They include a rich molluscan fauna, comprising 41 species of lamellibranchs and 28 species of gasteropods, of which the striking feature is the large proportion of forms either identical with or closely allied to those found in Europe. These indicate that the deposits are of Gault age and perhaps in part Aptian, but until the Ammonites have been studied more carefully, exact zonal divisions cannot be made. In addition to the Mollusca, calcareous Algæ, Foraminifera, corals and echinoids are also found. The faunal

assemblage in some of the deposits includes numerous examples of a Rudistid lamellibranch (*Præcaprotina*), abundant reef-building corals and *Orbitolina*, recalling the Urgonian facies of Europe

New Type of Filament Hygrometer. In the course of a paper read at the Royal Society of Arts on January 23, entitled "Humidity, Health, and some New Inventions", Mr C L Burdick described a new form of filament hygrometer (*J Roy Soc Arts*, Feb 22, 1935) As is well known, old pine cones continue to open and close with changes of humidity This is due to the fact that the outer layer of the conifer scale or bract consists of highly hygroscopic fibres, which lengthen when moisture is absorbed and shorten with desiccation, and with suitable cone fibres treated so as to oxidise remaining traces of resin, a high degree of reaction to moisture can be obtained Using these treated cone fibres, Mr Burdick has constructed several types of hygrometer With hair, linen or cotton thread, paper or vellum, and gold beater's skin, all of which have been utilised for the construction of filament hygrometers, the zero point undergoes considerable alteration in course of time, but cone fibres have been found to remain almost constant during a period of two years, and the cone fibre in its reaction to moisture has three times the linear contraction and expansion of hair, and is practically non-elastic

Nature of Lightning Discharges In a recent paper on this subject (*J Franklin Inst*, December 1934), Dr Harald Norinder describes the application of the cathode ray oscillograph to the recording of the electric field changes caused by lightning flashes For this purpose the author has used the oscillograph and technique which he developed a few years ago for the study of lightning and other surges on electric power transmission lines A horizontal antenna, suitably damped, was connected to earth through a high resistance, across which the deflecting plates of the oscillograph were connected. The time scale used with the oscillograph gave a sweep time which could be varied from 10 to 10^4 microseconds The paper referred to above gives an account of the results obtained from some 290 oscillograms of lightning discharges, many of which are illustrated It is shown that a lightning flash consists of a series of partial discharges, the duration of which may range up to 200 micro-seconds. When these partial discharges are examined on the high-speed records, they are seen to be of a quasi-oscillatory nature having a period of the order of 60 micro-seconds, with superimposed variations of a duration of 1 or 2 micro-seconds. An analysis has also been made of the polarity of the discharges, and the resulting net field changes At a distance of 2–7 km from the lightning flash, the variation of electric field intensity was found to be of the order of several hundred volts per metre.

Induced Radioactivity. Mr Wenh Yeh, writing from the Institut de Biologie Physico-Chimique, 1 rue Pierre Curie, Paris, sends us details of a classification of isotopes which shows that there is a continuous sequence of radioactive isotopes from $_3Li^8$ to $_8O^{15}$, whereas from $_9F^{18}$ to $_{17}Cl^{47}$ the unstable and stable isotopes alternate, this sudden variation in the sequence affording some evidence of a change in the nuclear structure beyond oxygen. The classification cannot be extended beyond chlorine owing to the lack of experimental data A shell model of the nucleus proposed by Mr Yeh (*Comptes rendus*, **199**, 1209, 1404, 1934) suggests that $_{19}K^{40}$ is formed from $_{19}K^{39}$ by neutron capture, the unstable $_{19}K^{40}$ disintegrating with the emission of positrons, or electrons, into $_{18}Ar^{40}$, or $_{20}Ca^{40}$ Recent work by Klemperer (*Proc Roy Soc*, A, **148**, 638, 1935) indicates that probably the relatively rare isotope K^{40} is responsible for the β-ray activity of potassium A communication upon the same subject has been received from Mr S Nishida, who writes from Konan-Koto-Gakko, Motoyamamura, near Kobe, Japan Applying the Landé neutron shell nuclear structure to the light elements, Mr Nishida finds that the radioactive isotopes which emit negative electrons possess neutrons in excess of those required to complete an inner shell, whereas positive electrons are emitted from those isotopes which have incompleted shells Accordingly there are two types of electron emission, namely, (a) a reaction in which an α-particle is formed with γ-ray emission, for example, $_{11}Na^{24} \rightarrow {}_{12}Mg^{24}$, (b) the formation of a proton and a deutron, for example, $_{12}Mg^{27} \rightarrow {}_{13}Al^{27}$ In addition, two types of positive electron are possible, in each reaction a proton loses a positron and so an additional neutron is produced, for example, $_7N^{14} \rightarrow {}_6C^{13}$, $_{15}P^{30} \rightarrow {}_{14}Si^{30}$ The proton within the nucleus, if associated with zero or one neutron, is unstable, being converted into a neutron with the emission of a positive electron This suggests that a proton may be formed by the combination of a neutron and a positron

Combustion of Carbon Monoxide. The catalytic action of moisture in the reaction $2CO + O_2 = 2CO_2$ has been clearly realised since the researches of H B Dixon, and different explanations of it have been given W F Jackson (*J Amer Chem Soc*, **57**, 82, 1935) has made experiments with the object of gaining knowledge of the steps postulated in the chain mechanism involving hydroxyl radicals and hydrogen atoms according to the scheme

$$(1)\ OH+CO=CO_2+H\ ;\quad (2)\ H+O_2+CO=CO_2+OH.$$

An electrical discharge through moist hydrogen or water vapour provides a reliable source of hydrogen atoms, and there is some evidence that hydroxyl can be drawn from the water discharge It was found that carbon monoxide was oxidised by the products of an electrical discharge through water vapour Numerous substances are present during such a discharge, and the discussion of the probable effects of these shows that several of them could not well be assumed to act as catalysts in the oxidation of carbon monoxide. Atomic hydrogen is shown to cause oxidation but it is considered probable that the reaction does not occur directly according to equation (2) but in two steps, with the intermediate formation of HCO or HO_2 It was found that the products of the action of the discharge on water vapour at pressures below 1 mm. cause the oxidation of carbon monoxide even when they have been drawn several decimetres from the discharge One of the products of such a discharge is shown to be hydrogen peroxide It is considered possible that OH radicals may be withdrawn in sufficient concentration to account for the fraction of the carbon dioxide yield which cannot be attributed to hydrogen atoms.

Archæological Excavations in Iraq*

IN the season 1932–33, which is covered by the third preliminary report of the director, Dr. Henri Frankfort, the Oriental Institute of Chicago was responsible for three major investigations in Iraq—at Tell Asmar, Khafaje and Khorsabad, and to the last of these were subjoined two minor investigations at Tepe Shenshi and Jerwan, to which the attention of the field staff was turned when, towards the close of the season, the weather precluded further activity in southern Iraq

The results of the season 1932–33 fully confirmed the impression which had been formed in the previous season that the site at Tell Asmar, the ancient Eshnunna, is likely to prove one of the most important in the south. Not indeed that it is probable that it will eclipse Ur in the richness of the finds or in the imposing character of the buildings; but, on the other hand, the evidence which it has already afforded indicates that it will be of first rate significance in the elucidation of a number of problems of Mesopotamian prehistory

Of these problems one of the most vigorously debated has been the dating of the Royal Tombs at Ur. According to the interpretation of the evidence from Tell Asmar by Dr Henri Frankfort, this must now be placed much lower than has been proposed by Dr L. Woolley, though it does not demand the extreme reduction favoured by some authorities At the time of writing this third report, Dr. Frankfort was not yet in a position to formulate a final judgment, but he was able to show that the evidence pointed to a contemporaneity of the tombs at Ur with the fifth stratum of his series at Tell Asmar, that is, the stratum preceding the Sargonid period. A possible date would, therefore, be c. 2700 B.C as against the c 3500 B.C. which commended itself to Dr Woolley.

The conditions of excavation at Tell Asmar were peculiarly favourable to determining chronological questions, they were such as to afford a basis of greater certainty than could be obtained from the excavation of a cemetery. The northern hills of Tell Asmar had not been inhabited in the Larsa period, or later, while in the extreme north a large building and a group of private houses south of it had been partially uncovered It was, therefore, possible to extend the excavations over a wide area and to avoid generalisation on a single example. At the same time, stratification could be determined with certainty This latter factor is of special importance, as it was found, in working out the plan of the city, that stratification was not a mere matter of determining absolute levels Constant rebuilding of structures fallen into disrepair over a long period of time had been responsible for differences in level, sometimes of a metre or more, between buildings of the same cultural epoch A further cause of a possible confusion was the survival of archaic features into periods to which they did not belong This was found to be due to the adaptation of the ruins of older structures as supports for the new.

In two respects in particular, the season's excavations at Tell Asmar are of outstanding importance for the cultural history of early Mesopotamia—the view they afford of the conditions of life of the private citizen; and, secondly, in the new knowledge they have yielded of early phases of religious cult and belief.

The conditions of life among the ordinary citizens are revealed in the remains of the large number of private dwellings which have been uncovered. From these the excavators have been able to determine or infer the lines of a fairly complete plan of the city, and at the same time to reconstruct the typical dwelling of the Sumero-Akkadian culture So far as the private dwelling is concerned, it is noted that there appears to be no marked break in occupation with the incoming of the Sargonid era, and it continued uninterrupted down to the period of the Third Dynasty of Ur, but in the area of the large building, which Dr Frankfort considers sufficiently extensive and complex to justify the denomination 'palace', there is a period of apparent abandonment represented by about a metre of rubbish which intervenes at the close of the Sargonid period

The reconstruction of the Akkadian dwelling-places emphasises several interesting features in the arrangement and relation of the various chambers. They differ from buildings at Ur in the absence of the open courtyard Two notable additions are made to knowledge of the architectural accomplishments of this early period in the form of a window, lighting a store-room by means of a terra-cotta grillo, and the use of the arch in communicating doorways. In both instances this is the earliest known example in Mesopotamia. In the 'palace' building by far the most remarkable structural feature is the sanitary system, in which, however, Dr. Frankfort notes, in the greater number of instances, the rooms are not congruous with this use

The excavation of the 'Temple of Abu', the temple of the god of fertility, has provided some remarkable material bearing upon the early form of religious belief in Mesopotamia, of which, however, the full significance is to be completely appreciated only when it is brought into relation with the cult material obtained from the private dwelling houses The unity of 'public' and 'private' cult is striking. The salient fact which emerges is that this Sumero-Akkadian religion centres around one deity; although, it is true, at this time the existence both of a great mother goddess and of a sun-god was recognised The god of fertility, however, is the central figure of the pantheon He personifies the generative forces of Nature and is closely associated with the crops and flocks and herds It follows that the various names of deities, Ninurta, Ningirsu, Abu Dumuzi (Tammuz) and the like are in reality but epithets referring to different aspects of this early deity, and tradition may have decided which aspect was to prevail in any given locality. Hence also it is clear that this fertility god was a Sumerian and not a Semitic deity. Not only was he the generative force in Nature, manifest in the fertility of the soil and the flocks, but also he lived in the netherworld, often assumed the shape of a serpent, was exposed to dangerous encounters, and vanquished monsters. From this last manifestation Heracles, it has been shown, stands in direct line of descent. The

* Iraq Excavations of the Oriental Institute, 1932–33: Third Preliminary Report of the Iraq Expedition. By Henri Frankfort. (The Oriental Institute of the University of Chicago Oriental Institute Communications, No 17) Pp ix+92 (Chicago: University of Chicago Press, London Cambridge University Press, 1934) 7s net

consummation of his marriage with a goddess was an essential part of the annual ritual. This ceremony was well known from other sources, but Tell Asmar has afforded on a seal the only known representation of the divine nuptials in early Mesopotamia.

Among a hoard of copper objects enclosed in a pot was a bronze open-work dagger-handle in which was wedged a fragment of the original blade This has been examined by Dr C H Desch, who pronounces it to be iron of telluric origin As it belongs to the 28th century B C, it is by many hundreds of years the earliest example known The same applies to a fragment of clear glass which has been examined by Mr Horace C Beck, who points out how surprising it is to find in Mesopotamia clear glass dating from 2700 B C, since in Egypt, although opaque glass was known in the second millennium B C, clear glass was not introduced before Roman times

It has been possible to touch only on the more striking points in Dr Frankfort's report, while the excavations at Khafaje and Khorsabad must be passed over, notwithstanding their interest and importance The excavations of the Oriental Institute closed for the season in 1933 at a point which promised much in the following season This expectation was not disappointed and the further reports of the director are awaited with interest

Three-Colour, One-Exposure Camera

THE customary method of making a set of colour-separation negatives for colour photography is by successive exposures on separate plates through the appropriate colour filters Usually three negatives are required This method fails for snapshot exposures of moving objects For many years inventors have attempted to devise three colour cameras operating with a single exposure during which all three images are simultaneously recorded Several of the optical devices which have been used to achieve this end were briefly described by Dr D A Spencer in 1933 (*Photographic J*, 74, 103, 1934) and a further method was described in 1934 (*ibid*, 74, 244, 1934) by the late Mr W T P Cunningham

One of the less difficult methods depends on the use of two inclined, semi reflecting, plane mirrors Light from the camera lens strikes the first mirror and a portion of it is deflected to form an image on one of the photographic plates placed behind its suitable colour filter; the remainder of the light goes on and meets the second mirror, which deflects a portion on to another plate, and the remainder goes on to the back of the camera where the third filter and plate are situated One objection to this method is that reflection takes place at both surfaces of each mirror and, if the mirrors are thick, double images may be formed This has led to the use of thin pellicle mirrors which are said to have been suggested by Geisler so long ago as 1910 (see Spencer, *loc cit*) and have recently been made as commercial articles by Mr H O Klein It is said that other ways of avoiding double images with this general arrangement of semi reflecting mirrors are also available.

The method has therefore led to considerable practical success and at present there are available two cameras which make use of it These were both shown at the recent British Industries Fair One is the Taylor Hobson three colour camera (Vivex system) and the other is the Klein tri-colour camera invented by Adrian B Klein and manufactured by Messrs Bellingham and Stanley, Ltd These cameras are said to work successfully to give exposures ranging from 1/25 sec to 1/10 sec in winter sunshine Inquiries about these cameras should be addressed, in relation to the first to Messrs Colour Photographs (British and Foreign), Ltd, Victoria Road, Willesden, N W 10, and in relation to the second to Messrs Farquhar and Moloney, 15–16 Newman Street, London, W 1, or to Messrs Bellingham and Stanley, Ltd, 71 Hornsey Rise, London, N 19

A Japanese Scientific Expedition to Manchoukuo*

THE Japanese have lost no time in examining the resources of the new 'independent' kingdom of Manchoukuo, and in October and November of 1934 were published in Tokyo the early sections of a report upon the first Japanese scientific expedition to the country, which carried out exploration work with the aid of motor transport and some aeroplane reconnaissance during the period June to October 1933. Under the leadership of the geologist, Prof Shigeyasu Tokunaga, of Waseda University, thirteen scientific workers representing geography, botany, zoology and anthropology were dispatched from Japan, largely through the influence of Viscount Toki, Vice-Parliamentary Secretary of the War Office. Never before has a scientific expedition been dispatched abroad from Japan on so big a scale The reports now published are in Japanese with a very full transcript in English, which manages to express some of the enthusiasm with which the expedition has undertaken its task, regarded as important both on patriotic and scientific grounds.

Before leaving Tokyo on July 22 the members of the expedition assembled in Tokyo in front of the 'Niju Bashi' (bridges at the entrance of the Palace) and worshipped at the entrance of the Palace; by July 30 they were in Hsin-king, the capital of Manchoukuo, and there they met again on October 12 "amidst the tear-prompting, enthusiastic welcome of the Government officials as well as plain people". On October 11 in the presence of Viscount Toki "the expedition drank to the happy completion of the scientific investigations at the risk of lives" During the intervening seventy days, some 5,000 kilometres had been covered in automobiles over trackless country; "the bottoms of the rivers are rather shallow [elsewhere described as "abdomen-deep"], yet the quagmire-bed so deep The treacherous rivers!" So far as possible they drove

* Report of the First Scientific Expedition to Manchoukuo under the Leadership of Shigeyasu Tokunaga, June–October 1933 Section 1: Natural Science Research of the First Scientific Expedition to Manchoukuo. By Shigeyasu Tokunaga Pp iii+76+69 plates Section 4, Part 1: Plantae Novae Jeholenses, I By Takenoshin Nakai and Masao Kitagawa. Pp iv+71+20 plates Section 5, Part 1 The Fresh Water Fishes of Jehol. By Tamezo Mori Pp ii+61+21 plates. (Tokyo Waseda University, 1934)

along the dry beds of rivers, but frequent storms, which in Jehol turned scorching summer to bitter cold, often delayed or prevented a projected tour ' A proverb goes 'a precipice in front, a wolf behind', when our march was impeded, we could not safely stay where we were because of there being a danger of bandits' assault". The expedition's work was done under escort of thirty soldiers and occasionally under additional protection from garrisons

Dirty and scarce drinking water, and ' horribly poisonous insects", with the concomitant troubles of dysentery, trachoma, etc, were probably greater difficulties than the bandits, who only fired upon a camp on one occasion An endemic epidemic goitre was found to be widespread in south-western Jehol

The preliminary scientific results are summarised by the head of each section in the first general report (October 1934) A brief stratigraphical summary reports abundant fossil *Lycoptera* and many fossil insect larvæ (*Ephemeropsis*) in lower Cretaceous rocks In loess strata of Middle Pleistocene age, remains of *Ovis* and *Elephas* included bone pieces apparently engraved by ancient man Jehol was a nomad zone originally occupied by Mongolians, during the Shin dynasty, these Mongolians had declined in prosperity and the Hans (Chinese in the Han dynasty) emigrated there In the northern district of Manchoukuo the Mongolians still predominate, and throughout the country three systems of farming can be traced, the North Chinese, Manchurian and Mongolian The animals found still recall the forests, which have been ruthlessly despoiled since the Hans. The November report (Section 4, Part 1) figures and describes eight species of new woody plants (by Dr T Nakai) and twenty-nine new herbaceous plants (by Dr T Nakai and M Kitagawa)

Section 5, part 1, consists of an account of the freshwater fishes of the province of Jehol This province—a highland area occupying the south-western part of Manchoukuo and contiguous with the north-eastern border of the Chinese province of Hopei (Chili)—is irrigated by the upper reaches of several rivers in the waters of which and those of associated lakes and ponds 783 fishes were collected These comprised 33 species and one sub species representative of the two families Cyprinidæ and Ophicephalidæ. The detailed taxonomic descriptions are accompanied by twenty-one beautifully produced plates in which all the species are carefully figured, some of them in colour.

Lubricating Value of Mineral Oils

IN 1929, under the auspices of the Department of Scientific and Industrial Research, a paper (Lubrication Research, Technical Paper No. 1) by the late Sir William Hardy and M E Nottage on the analysis of commercial lubricating oils by physical methods was prepared It was considered, however, inadvisable to draw conclusions from the results of experiments reported therein, since only two oils, and those of unknown origin, had been employed. A further paper by Miss Nottage recently published under similar conditions (Lubrication Research, Technical Paper No. 2. London: H M. Stationery Office. 9*d*. net) entitled "A Study of the Boundary Lubricating Value of Mineral Oils of Different Origin" is intended in certain respects to supplement the original one.

When the film of lubricating oil separating two smooth bearing surfaces is so thin that no part of it is beyond the range of cohesive forces of attraction transmittable from these surfaces, boundary conditions are said to prevail Interposition between the two surfaces of a film of oil may, to some extent, neutralise these conditions or, in other words, boundary lubrication may be employed. In these circumstances two important factors must be taken into consideration the effect of the surface on the oil, hence the nature of the bearing surface, since chemical activity occurring at an interface differs materially from that occurring in bulk, and chemical properties of the lubricant, the function of which of neutralising the cohesive forces of attraction is effected by the formation of adsorptive layers on the bearing surfaces

Inasmuch as mineral lubricating oils consist of inactive, non-polar constituents and surface-active polar constituents, from which the greater part of the adsorptive layer is formed, the properties of the film may differ considerably from properties of the oil in bulk Important factors determining friction-reducing properties of the adsorptive layer are the chemical nature of the constituents and their degree of dispersion. This, in turn, may be varied by changes of temperature, the presence of other substances which play no part in reducing friction, or the solution of oil in certain volatile solvents

Having regard to the important part played by wax in mineral oils, concurrent investigations were made to obtain some indication of its rôle in a lubricant under boundary conditions. It is shown that, in spite of the general view that wax is detrimental to a lubricant, it does, in certain cases, enhance the lubricating value of the oil at the boundary layer.

University and Educational Intelligence

CAMBRIDGE—At St John's College a research studentship and research exhibitions are offered for competition in July 1935 One Strathcona research studentship of the annual value of £150 is offered for competition among research students who are graduates of any university other than Cambridge Two Strathcona exhibitions of the annual value of £40 are also offered for competition under the same conditions as the studentship

Grants from the Worts Fund have been made as follows:—£75 to D B Keith, A B Whatman, and J W. Wright towards the expenses of an expedition to survey the north coast of North-East Land (Spitsbergen); £120 to P. T Cotton, D W. Ewer and L E R Picken towards the expenses of an expedition to investigate the freshwater ecology of the south-west Balkans, £50 to T. T Paterson towards the expenses of an expedition to the North-West Frontier of India for the purpose of studying quaternary deposits; £26 10*s* to J R B Stewart for archæological investigations in Asia Minor; £25 to Dr T. C Phemister towards the expenses of a geological and petrological survey of the Coast Range batholith of British Columbia; £25 to T. G Tutin for a visit to the Mediterranean coast of Spain to study the destruction of the eel-grass, *Zostera marina*; £25 to K H Chapman for an expedition to Morocco to study the Moroccan locust, *Dociostaurus morocannus*.

J. H. Lockhead, of Christ's College, has been nominated to use the University's table at the Zoological Station at Naples.

LONDON.—Mr. R. O. Kapp has been appointed as from March 1 to the Pender chair of electrical engineering tenable at University College.

THE Board of Education is prepared, as in recent years, to consider applications for full-time studentships from teachers in England and Wales with at least five years teaching experience who desire financial assistance to follow courses of advanced study at universities or other institutions at home or abroad. Particulars of the awards and application forms are obtainable from the Board of Education, Whitehall, S.W.1.

APPLICATIONS, which must be received not later than April 15, are invited for the following scholarships awarded by the Council of the Institution of Electrical Engineers. Further particulars can be obtained from the Secretary of the Institution, Savoy Place, London, W.C.2. Duddell Scholarship, valued at £150 a year and tenable for three years, open to British subjects under nineteen years of age on July 1, 1935, who wish to take up a whole time day course in electrical engineering; Ferranti Scholarship, valued at £250 a year and tenable for two years, open to British subjects under twenty six years of age on July 1, who desire to carry out whole-time research or post-graduate work in electrical engineering. Swan Memorial Scholarship, valued at £120, and for one year, open to British subjects under twenty seven years of age on July 1, who desire to carry out whole-time research or post-graduate work in electrical engineering. Silvanus Thompson Scholarship, valued at £100 a year and tuition fees, tenable for two years, for works employees, open to British subjects under twenty-two years of age on July 1; the successful candidate will be required to take up a whole time day course in electrical engineering at an approved university or technical college.

FROM Heriot-Watt College, Edinburgh, we have received a brochure signalising the completion and opening, in January, of the first section of an important extension of the College buildings, planned, in conjunction with the Town Council, in 1928. The second section, to be completed, it is hoped, in 1936, has already been begun, and the governors propose to make now an appeal for the sum of £100,000 to finance the construction and equipment of the final section. The appeal will be associated with the celebration of the fiftieth anniversary of the assumption by the College of its present name and functions. Prior to 1886, the institution was concerned mainly with evening classes for young persons employed during the day in earning their living, and without any other means of advancing beyond the standards of education of the elementary schools. The pamphlet gives, in addition to full particulars of the extension scheme, a very interesting account of the stages through which the 'School of Arts', founded in 1821 by Leonard Horner (afterwards first principal of University College, London), gradually reached its present status—that of an affiliated college of the University of Edinburgh, preparing students for careers in mechanical, electrical, mining and oil engineering, applied chemistry, brewing, pharmacy, building and printing and conducting evening classes in commerce. Special prominence is given to the amplitude, due in large measure to the exertions of the late Edward Clark, of the equipment of the printing school for the teaching of all phases of book production.

Science News a Century Ago

Chemistry of the Sea

The chemical composition of sea and mineral waters was being actively investigated by Dr. Daubeny in the years 1835–37. In his manuscript "Note-book of Experiments" he records, "March 25th. Having brought from Naples a bottle containing the residuum of 2 gallons of the sea water taken off the Island of Ischia evaporated till there remained only 6 ounces, I tested it for Bromine . . . I obtained 5.1 grains of silver precipitate—chiefly bromide." From previous analyses it appeared that there is an almost exact correspondence between the quantity of bromine present in the sea water off Southampton and off Naples.

Temperature of Fishes

Dr. John Davy (1790–1868), the brother of Sir Humphry Davy, became an army surgeon and rose to the rank of inspector-general of army hospitals. He was eminent as a chemist, geologist and physiologist, and in 1834 was elected a fellow of the Royal Society. On March 26, 1835, he read a paper to the Royal Society "On the Temperature of some Fishes of the Genus Thunnus". He said that many years before he had observed that the bonito had a temperature of 99° F. when the surrounding medium was 80.5° F. and that it, therefore, constituted an exception to the general rule that fishes are universally cold-blooded. Having found that the gills of the common tunny of the Mediterranean were supplied with nerves of unusual magnitude, that the heart of this fish was very powerful and that its muscles were of a dark red colour, he was led to conjecture that it might, like the bonito, be also warm-blooded, and this opinion was corroborated by the testimony of several intelligent fishermen. In the course of his paper he endeavoured to extend the analogy to other species of the same family which, according to the reports of the fishermen of whom he made inquiries, have a high temperature and in the internal structure of which he noticed the same peculiarities as in the tunny, namely, very large branchial nerves, furnished with ganglia of considerable size.

Faraday on the Manufacture of Pens

On March 27, 1835, Faraday lectured at the Royal Institution on the manufacture of pens. A report of the lecture was given in the *Records of General Science* of May 1835. Quills, Faraday said, appear to have been employed at least as early as the seventh century. England was supplied with the article from Russia and Poland, where immense flocks of geese were kept for the sake of their quills. Twenty million quills were imported into England from those countries in 1834. A wing of a goose produced about five good quills, and by proper management, a goose might afford twenty quills during the year. The preparation of quills was a nice process of which, up to seventy years previously, the Dutch had had a monopoly. A pen cutter would cut about 1,200 quills a day. A house in Shoe Lane cut annually about six million. Steel pens for writing were first made by Mr. Wise in 1803, and were fashioned like goose pens. A patent was taken out in 1812 for pens with flat cheeks, and in this way all metallic pens were made for some time, as the rhodium pen of Dr. Wollaston and the iridium pens of others. About twelve years

previously, Mr Perry began to make pens, and about six years after that they were manufactured in Birmingham Faraday described the processes employed in the making of steel pens and said that, from information given him, the total quantity of steel used in Great Britain for pen-making was 120 tons When first introduced, steel pens were 8*s* a gross, but recently they had been manufactured at 4*d* a gross It appeared that the only interest that had suffered by the employment of steel pens was that of the pen-knife makers

Samuel Clegg and the Gas Industry

In the *Mechanics' Magazine* of March 28, 1835, is a contribution from "L. L" on "Materials for a Memoir of Mr Samuel Clegg, and Authentic History of the Art of Gas Lighting" Samuel Clegg, the older, was born in 1781 and died in 1861, and "L L" described himself as one of his earliest and oldest friends Clegg learnt the art of gas-making from Murdoch at the works of Boulton and Watt In 1805 he set up a small gas plant at his mother's house in Manchester, and in the following year installed gas lighting in some of the Lancashire factories He was the first chief engineer of the Gas Light and Coke Company and he was the first to invent a gas meter In the course of his article "L L" said "In 1814 Mr Clegg superintended the fitting up of the pagoda in St James's Park This splendid display of the power of gas illumination was exhibited to the Royal family on the evening previous to the night when it was burned down by the fireworks The pagoda was an octagonal figure, 80 feet high from the bridge At each angle there was a pipe running the whole height, with a small hole drilled every two inches, through which gas issued, and opposite each of the lowest holes in the perpendicular pipes was placed an oil lamp, concealed by a piece of sheet iron, so that when the gas was turned on, the first flame was ignited by the oil lamp, and each gas flame lighted the one immediately above it all the way to the top This gave the whole the appearance, when first lighted, of so many rockets ascending into the air There certainly never was anything so beautiful before, and it is likely that there never may be again "

Societies and Academies

LONDON

Royal Society, March 14 M L E OLIPHANT, A E KEMPTON and LORD RUTHERFORD The accurate determination of the energy released in certain nuclear transformations. If changes of mass are taken into account, the law of conservation of energy holds closely for the transformations of the isotopes of lithium when bombarded by ions of ordinary and of heavy hydrogen The masses of Li^6 and Li^7 are found to be 6 0143 ± 0·0002 and 7 0148 ± 0 0002 respectively, in good agreement with the mass spectroscopic values 6 0145 ± 0 0003 and 7·0146 ± 0·0006 found by Bainbridge By application of the laws of conservation of momentum and energy, the mass of the hydrogen isotope of mass 3 is found to be 3·0152 ± 0·0002. Attention is directed to the factors involved in determining the mean ranges of expelled particles and to the difficulties of interpretation when more than two particles are emitted in a single transformation While there is good agreement in the case of lithium, which involves the masses of particles measured in terms of helium, a number of nuclear reactions in beryllium and other elements show large discrepancies on the accepted mass scale. These reactions, as well as those in lithium, can be brought into line by assuming a small error in the helium oxygen ratio H J TAYLOR. The tracks of α-particles and protons in photographic emulsions α-particles and protons give tracks in photographic emulsions, which are visible, after development, as rows of grains in straight lines These tracks have been studied, using special emulsions more suitable for such work than those commercially obtainable. Exposure of a plate to a neutron source gives rise to well defined tracks, which are due to the protons ejected by the neutrons in their passage through the gelatine of the emulsion The method is, however, unsuitable for quantitative study of neutron energies

PARIS

Academy of Sciences, February 4 (*C R*, **200**, 429–500) The president announced the deaths of Charles Flahault, non resident member, and of Theobald Smith, *Correspondant* for the Section of Rural Economy B HAVLKA The curves in Euclidian space of n dimensions the curvatures of which are connected by linear relations with constant coefficients JEAN LOUIS DESTOUCHES Conditions to be imposed on a physical space and the generalisation of Poincaré's definition of the number of dimensions HENRI ROURE The calculation of a periodic solution in the perturbation of Pluto by Neptune F TESSON · A liquid microcathetometer The distance between two vertical points is measured by running water from a microburette into a circular trough containing water covered with a layer of oil Contact with the point can be determined to 0·001 mm and, by arranging a suitable area for the section of the trough, this corresponds to the addition of 0·02 c c of water AMÉDÉE GUILLET The measurement of the moment of a couple by the use of the chronometric motor Application to the study of viscosity MARCEL CHRÉTIEN A new apparatus for the restitution of aerial photographs LÉONARD SOSNOWSKI The radioactivity excited by neutrons in platinum The neutrons in the experiment described were obtained from irradiated beryllium Platinum, after 15 hours exposure, gave a radiation which from its rate of decay and absorption on passing through aluminium, would appear to be due to β-particles PIERRE AUGER and A ROSENBERG The secondary effects of the cosmic rays FRANCIS PERRIN and WALTER M ELSASSER The theory of the selective capture of slow neutrons by certain nuclei PIERRE MONTAGNE: The calculation and graphical representation of the elementary displacements in the reactions of homogeneous chemical equilibrium Variation of the concentrations Reactions at constant volume RAYMOND LAUTIÉ · The molecular weight of a pure liquid at its normal boiling point PAUL LAFFITTE and PIERRE GRANDADAM · The oxides of platinum The authors have previously described the preparation of a mixture of the two oxides PtO and PtO_2 by the direct action of oxygen at high pressure and at a high temperature on platinum The dioxide was isolated from this mixture and in the present communication the isolation of PtO is described Hydrogen reduced PtO instantaneously at the ordinary temperature The mixed oxides act as a very active catalyst in the hydrogenation of certain organic

compounds FÉLIX TROMBE: The isolation of gadolinium. The gadolinium is separated by electrolysis of its chloride in the presence of cadmium: the cadmium is afterwards removed from the gadolinium by distillation in a high vacuum. MARCEL CHÂTELET: A transition compound in the formation of complex compounds of trivalent cobalt. PIERRE FRÉON: The preparation of α-aldehyde alcohols. The Grignard reaction takes place normally with α isonitrosoketones, and the aldehyde alcohol $C_4H_9C(CH_3)(OH)CHO$ has been prepared by this method. GERARD DESSEIGNE: The condensation of isopropyl alcohol with toluene and some substitution derivatives. GEORGES DARZENS and ANDRÉ LÉVY: The synthesis of a methylmethoxytetrahydronaphthalenic acid, the corresponding naphthalenic acid and of 1.7 methylnaphthol. GEORGES MIGEON: The proportion of water and the dehydration of sepiolites. V. BABET: The first fossil molluscs collected in French Equatorial Africa, in the formations of the interior basin of the Congo. JOSEPH BLAVAC, RODOLPHE BOHM and GASTON DELÉPINE: The age of the Lydian horizon of the base of the Carboniferous of the Montagne Noire. ALBERT ROBAUX: The presence of the Upper Cretaceous at the base of the Flysch series of the south of the province of Cadiz. E. FOURNIER: The experiment with fluorescein at the Paradis gulley (Doubs). The fluorescein test showed that the water from this gulley appeared at four outlets, taking from three to eight days to travel. JEAN CUVILLIER: The distribution and stratigraphic value of *Nummulites uroniensis* in Egypt and in the Mediterranean basin. FRON and MONCHOT: The influence of certain derivatives of quinoline on vegetation. The neutral sulphate of ortho-oxyquinoline (cryptonol), which is known to possess a powerful anticryptogamic action, when added in suitable proportions to soil, hinders the development of injurious fungi and does not reduce the fertility of the soil. ARON POLACK: The disadvantage of didymium in optical glasses. YVES LE GRAND: The measurement of acuteness of vision by means of interference bands. A. DORIER: The passage to latent life of the larvæ of the Gordiaceæ. HENRI HEIM DE BALSAO: The line of demarcation between the Berber and Saharan fauna in North Africa. Its ecological determinism. JAMES BASSET, MICHEL MACHEBŒUF and JEAN JACQUES PEREZ: Studies on the biological effects of ultra-pressures. Modification of the antigenic specificity of serums under the influence of very high pressures. MICHEL FAGUET: The photometric study of microbial multiplication.

LENINGRAD

Academy of Sciences (*C.R.*, 4, No. 7). A. MAYER and E. LEONTOVICH: Some inequalities relating to Fourier's integral. I. VERCHENKO and A. KOLMOGOROV: Further investigations on the point of inflexion of functions of two variables. L. RADZISHEVSKIJ: A method for investigating certain classes of integral equations and of systems with an infinite number of unknown quantities. A. POPOV: Some types of series. J. SEDOV and A. FILIPPOV: Optical dissociation of indium bromide and indium iodide. L. GROSHEV: The spectral distribution of photo-electric current in salts dyed by colloidal copper. S. ARTSYBYSHEV, L. MILKOVSKAJA and M. SAVOSTJANOVA: The influence of illumination on the formation and destruction of colloids of sodium in rock salt. A. PETROV and T. BOGOSLOVSKAJA: Problem of the chemistry of voltol oil formation. G. TARASOV: Polymerisation of liquid hydrocarbons under the action of electric discharges. P. BUDNIKOV and L. GULINOVA: Methods for the determination of active silica in pozzolanic substances. M. BRIK: A find of Lower Triassic flora in Central Asia. N. FILIPJEV: Lepidopterological notes (16) A case of nomenclature.

SYDNEY

Royal Society of New South Wales, December 5. ADRIEN ALBERT: *Myoporum Deserti*: a preliminary investigation. *Myoporum Deserti*, otherwise known as dog-wood poison bush, Ellangowan poison bush, turkey-bush, etc., has been long suspected of being toxic to cattle. The fruits and the leaves contain a poisonous substance, probably of a glucosidic nature, which could not be isolated during the present work, but leaves and extracts of the leaves tested at Glenfield Veterinary Research Station have confirmed the toxicity of both leaves and fruits to calves and sheep. One pound of air dried leaves was fatal to the latter. A small amount of volatile oil containing an unidentified ketone was obtained from the leaves. J. C. EARL and G. H. MCGREGOR: A chemical examination of blackfellows' bread, the sclerotium of the fungus *Polyporus mylittæ*, Cke and Mass. The material was examined by acetylation and by degradation of the acetate with methyl alcoholic hydrochloric acid. The acetate closely resembled cellulose triacetate except that the specific optical rotation was slightly high. The principal degradation products were the methyl glucosides, but there was evidence of the presence of some other methyl glycoside. By direct acid hydrolysis of the original material, a solution containing glucose and some ketose sugar was obtained. The quantities of nitrogenous and other-soluble substances present were low. J. W. HOGARTH: A note on the decomposition of cobalt amalgam. A new cobalt amalgam, prepared by electrolysis of cobalt sulphate with a mercury cathode, at a high current density, when exposed to the air is rapidly oxidised to what appears to be a suboxide of cobalt. This latter substance is a fine, intensely black powder, yielding some hydrogen on treatment with dilute acid, and neutral water on reduction with hydrogen. T. H. HARRISON: Brown rot of fruits and associated diseases of deciduous fruit trees (2). The apothecia of the causal organisms. In continuation of his studies of the taxonomy of the brown rot fungi, the author presents a comprehensive account of the apothecial stage of the three common species of brown rot fungi, namely, *Sclerotinia fructigena*, Ader and Ruh., *S. laxa*, Ader and Ruh., and *S. fructicola* (Wint.), Rehm. A further record of each of the first two species is presented. Comparative studies of all three are reported and discussed. V. M. TRIKOJUS and D. E. White: Chemistry of the constituents of the wood-oil of the 'callitris' pines (2). Guaiol. Guaiol, from *C. intratropica*, $C_{15}H_{26}O$(i), on oxidation with potassium permanganate yields the dihydroxyether, $C_{15}H_{26}O_3$(ii), obtained by previous workers, and a substance, $C_{15}H_{24}O_3$, the function of the oxygen atoms being undetermined. (i) on oxidation with percamphoric acid gives $C_{15}H_{26}O_2$ in quantitative yield, a further indication of the presence of a double band or labile third ring in (i). The action of bromine (1 mol.) on (i), followed by hydrolysis, gives good yields of an inseparable mixture of $C_{15}H_{24}$ and $C_{15}H_{24}O$, which reduces catalytically to a mixture of the corresponding dihydroderivatives. Oxidation of guaiene, dihydroguaiene, or (ii) has not

led to positive results. ELINOR S HUNT A summary of changes noted in the allantoic membrane of the chick in 500 experiments The allantoic membrane of the embryo chick was prepared in the manner described by Moppett (*Proc Roy Soc* (B), **105**, 402; 1929) and exposed for periods varying from 2 hours to 6 days to the radiation from a 3 mgm. radium needle A comparison with controls exposed over a blank needle case clearly demonstrated a radiation effect for the longer exposures It was thought that mere exposure had a sensitising effect since many of the controls showed abnormalities An extended investigation with control specimens gave no evidence of infective changes but the incidence of abnormal specimens was greatly reduced by 'sheltering' the exposed area by placing face down on cotton-wool

Creative Thought and Social Service

MANY who listened to the national lecture broadcast by Dr T R. Glover on December 19 of last year on the challenge of the Greek must have recalled the plea for courage and magnanimity with which Sir Arthur Salter closed his "Recovery", and that rectorial address of General Smuts at St. Andrews on "Freedom", which should be among the enduring monuments of the literature of 1934 The adventure of the new age, the call to creative thought, to the untiring endeavour to give to every man the physical comfort, leisure and free access to all the world's rich heritage which he possesses the capacity to enjoy, demands courage and vision, but demands above all the individuality and freedom which were among the outstanding characteristics of the Greek

The note of adventure sounded in these addresses repays consideration To sustain any civilisation at a high level requires more than learning , it requires a search for new perfections, which is the element of adventure and avoids the tedium of indefinite repetition and repressing mechanisation Only the adventure of ideas and of practice conforming to these ideas can save a civilisation from decadence, and the first service that ideas can render is that of mental fertilisation —preparing the mind to receive the ideal of other types of perfection which in turn becomes a programme for achievement

This is the essential characteristic of creative thought—the provision of new ideas, new ideals, new forms of service It flourishes in an atmosphere of freedom and of adventure The real problem indeed is not that of producing great men but of producing great societies who will put up the men for the occasion, as Whitehead truly reminds us. It is just because over whole departments of life to-day the tradition of freedom is steadily weakening and individual initiative is being repressed that the world situation is so dangerous In the new experiments at government which are being tried out, the individual, as General Smuts pointed out, is more and more at a discount Individual freedom and independence of mind are essential to all real progress Without them neither science, art nor politics can flourish

This issue of freedom, the most fundamental of our civilisation, raised once again by the events of the last few years, cannot be evaded. The new forms of government which have sprung up on the Continent, and are urged elsewhere by political

groups, are based on a denial of liberty, not as a temporary expedient but on principle. It is the false assumptions on which these experiments are based, not the fact of experimenting, despite the risks in experimenting by those who have not been trained in the technique of experience, that is our danger ; and the warning given by General Smuts last autumn is as impressive as it is eloquent. Without freedom, "peace, contentment and happiness, even manhood itself, are not possible 'Happiness is Freedom, and Freedom is Courage' That is the fundamental equation of all politics and all human government and any system which ignores it is based on sand The vision of freedom, of the liberation of the human spirit from its primeval bondage, is perhaps the greatest light which has yet dawned on our human horizon It forms the real spur of progress, the lure of our race in its ceaseless striving towards the future Freedom should be a creative force inspiring our young men and women to noble action"

The experiments to which General Smuts refers are in some respects reactions from abuses or failures on the part of democratic or supposedly democratic institutions They are also attempts to save the State from the untoward consequences of such abuse or failure, but in doing so they offer merely a temporary security while jeopardising our fundamental human ideals and our finest heritage from the past Here, as so often, the deliberate search for security leads to an anæsthesia which conceals the paralysis and decay proceeding beneath the surface, all the more readily when uniformity of speech and conduct steadily limit and standardise thought

Many dangers attend this standardisation and mechanisation of life, but few are more serious than the opportunity they afford for shallow and specious doctrines to be imposed upon masses of mankind by a few groups the interests of which are served by their propagation The scientific worker at least should be alive to the danger which threatens him The limitation of scientific inquiry has been experienced in the past under the domination of theology The bondage of political theories and expediencies will prove no less deadly to scientific advance than the earlier fetters which science has long since shed, and for his own sake the scientific worker must not tamely watch their imposition. As General Smuts said in his address on February 9, read before the newly founded South African Institute of International Affairs (*The Times*, Feb 11), "in these grave developments we see not new life for the world but rather decay, not an enrichment of the European tradition but an impoverishment, a negation of the finest and noblest insights of human spirit, and a falling back rather than an advance in the great cause of civilisation".

The man of science, however, does not stand alone In these last few years, he has been rapidly learning to view his work in relation to society, to see it not as an isolate but as an integrated part of the functioning of society He has seen before him whole fields of society in which his method and habit of impartial investigation might be fruitfully applied, and indeed must be applied if society is to be secure under the conditions created by the growing application of scientific discoveries in the mechanical world These fields of work and these possibilities will disappear if the freedom of the individual continues to be restrained The direction or rather exploitation of scientific work in the interests of a single class or of existing political theories contains the seeds of its own disaster and downfall

Nor is this all If humanity is to reap the full results of scientific investigations, if the knowledge thus acquired is to be turned to account in the service of mankind, above all in the wide fields of sociology and politics, science has to join hands with art Civilisation requires beauty as well as truth, as well as adventure Even more than science, if possible, art demands the free expression of individuality. Science, it is true, rests largely on creative thought and individual enterprise, and under modern conditions is evolving a technique of team work which ensures their full play in the concentrated attack on a definite objective

Progress even here is thus founded upon the experience, the integration of discords, and the social value of liberty lies largely in its production of discords and stimulation of thought. Without such freedom and discord, art becomes impossible Art is essentially, as Whitehead has said, a finite fragment of human effort achieving its own perfection within its own limits It heightens the sense of humanity and evolves into consciousness the finite perfections which lie ready for human achievement. In its broadest sense, art is civilisation—the unremitting aim at the major perfections of harmony, the purposeful adaptation of appearance to reality Its secret lies in its freedom.

To surrender freedom is to dry up the fountain springs of creative thought in science and art alike, and to render impossible that alliance of science and art which is probably our supreme need if the results of scientific knowledge over the widest fields not merely of the physical but also of the biological and sociological sciences are to be applied wisely and impartially, and integrated into the structure of society. Well may General Smuts's words ring in our ears an insistent call to join issue at once with all those forces which menace so fair a prospect of advance, and jeopardise the noblest traditions and heritage which have come to mankind from the great civilisations of the past.

Reviews

The Anthropology of the Near East

An Introduction to the Anthropology of the Near East in Ancient and Recent Times By C. U Ariens Kappers With a Chapter on Near Eastern Bloodgroups, by Leland W Parr Pp vii+200+3 plates (Amsterdam: N V Noord-Hollandsche Uitgeversmaatschappij, 1934)

IN 1929 Dr Ariens Kappers, director of the Central Institute for Brain Research in Amsterdam, landed in Syria as a visiting professor in the American University of Beirut There he remained for a year lecturing on "Histology and Neural Anatomy"—for it is as a neurologist that he has made his world-wide reputation At Beirut he was tempted into a new field of inquiry—that of anthropology. Amongst his students he found representatives of that welter of races which has made the Near East the despair of the modern anthropologist Near at hand were the peoples of Syria—the Lebanese, the Druses, the Alouites along the coast to the north, the inhabitants of Damascus and of other Syrian cities on the border of the desert and the bedouin Syrians He had communities of Armenians, Jews and Arabs open to him for observation Near at hand was Palestine with its puzzling mixture of human types—old and new. He took the field, callipers in hand, and succeeded in measuring 2,500 individuals, representing the more outstanding racial types To his own measurements he added those made by others To obtain explanations of the data he collected in Syria, he found it necessary to extend his inquiries until they carried him far beyond the Caspian on one hand and the Persian Gulf on the other The results of his inquiries appeared as a series of papers in the *Proceedings of the Royal Academy of Science of Amsterdam* These researches have now been systematised and form the basis of the present work—"An Introduction to the Anthropology of the Near East". A very valuable chapter has been added by Dr. L W. Parr, of George Washington University, Washington, D C, in which is summarised the results of an investigation of the blood-reactions of Near Eastern race groups.

Before attempting to indicate the conclusions reached by Dr Kappers as to the number of races he has identified in the south-western part of Asia, and the relationships in which these races stand to each other, in an evolutionary sense, it is necessary to touch on the methods he has employed for the discrimination of one race from another His method has the recommendation of simplicity He takes two measurements of the head—its length and its width—and relies on the proportion which the width bears to the length to give him an indication of race He insists, however, and all anthropologists will agree with him on this, that when a group of measurements has been made the result must not be expressed in a single figure as a mean or average but must be tabulated so that the individual measurements are expressed in the form of a 'frequency curve'.

Dr Kappers regards the form of this curve as being indicative of race Just because the Turk, the Armenian, the Lebanese, the Druses, the Assyrians, the Uzbegs, the Kirghiz of Turkestan, and the round-barrow people of England have frequency curves which fall on the same range of the cephalic scale, they must be regarded as members of the same race—to which Dr Kappers proposes to give the name of "Central Asiatic". It would be difficult to find two peoples more sharply differentiated from each other than are the Armenians of Anatolia and the Kirghiz of Turkestan If we are guided by external appearances we shall assign the Kirghiz to the Mongolian stock and the Armenians to the Caucasian stock

Dr Kappers holds that the cephalic index—the relative width of the head—is a more reliable guide to race than are outward appearances After a lifetime spent in the study of cranial characters and racial traits, I have come to an opposite conclusion—namely, that external traits are better guides to race and to degrees of racial affinity than are the relative diameters of the skull. For example, if we are to judge the race of Charles Darwin according to his head form, then we must assign him to Dr Kappers' "Central Asiatic Race", but if we judge him according to standards accepted by his fellow countrymen we must regard him as a Caucasian of the English breed.

I am certain the majority of anthropologists

will agree with me that relative head diameters have not the racial values which Dr. Kappers has assigned to them I know, too, they will agree with me when I say that Dr Kappers has done anthropology an important service by the compilation and publication of his head charts—92 in number. Indeed, his book will serve better, perhaps, as an 'introduction' to the study of the cephalic index than to a knowledge of the peoples of the Near East He has also done a service by again directing attention to 'apices' or 'peaks' which appear with a certain degree of regularity in distributional curves of cephalic indices. When Dr Kappers had plotted out the cephalic index (relative head width) of 136 Armenians measured by him in Syria, he found his frequency or distributional curve rose into two strongly marked peaks, showing a preponderance of individuals at 83 and at 86 He was surprised to discover that these two peaks appeared in series of measurements made on Armenians living in lands outside Syria These peaks or apices were so constant that he felt confident they must have a significance But what significance? Dr. Kappers seeks to explain them by supposing that the Armenians represent a fusion of two races—one in which the mean index was at 83, the other at 86

There is no reason to suppose that such a fusion has occurred, and apparently Dr. Kappers is not entirely satisfied with this explanation, for he throws out the suggestion that evolution may work on the diameters of the head, not by running up or down a graded scale of diameters but by making jumps or mutations—just as we change gear in motor-cars by a series of big changes. For example, Dr Kappers observed when the 86 peak rose to a higher level on his curve than did the 83 peak, then a third peak usually appeared towards the end of the frequency curve This third peak was situated at 89 or 90 on the scale of cephalic indices Likewise in the frequency curves representing the cephalic indices of narrow-headed peoples If the 72 apex rose above that at 76, then an additional peak or apex usually appeared at 67, towards the lower end of the scale.

Dr. Kappers also accepts gross irregularity of a frequency curve as evidence that the people, represented by such a curve, is of mixed origin. For this reason he looks on the Samaritans of Nablus, who regard themselves as pure descendants of the pre-exilic Israelites, as a people of mixed race. Dr. Parr's investigation of the blood groups of the Samaritans was also unexpected in its results. The Samaritans showed no affinity to Hebrews or to any neighbouring Eastern people. Dr. Parr explains the peculiar blood-reactions of the Samaritans as a result of prolonged inbreeding. But if inbreeding gives irregularity in blood groups, it ought to give uniformity in cephalic indices. Or is it the case that biometricians are wrong in supposing that a high degree of variation in form and structure is indicative of racial mixture? May it not be that degree of variability may be a characteristic of a race that although genetically pure is tending to evolve into new forms? The study of human races, as is evident from such instances, has not reached the status of a science.

Particularly interesting are Dr Kappers' observations on the Jews. Among the northern Jews—the Aschkenasim—he found a considerable degree of round-headedness, whereas among the southern Jews—the Sephardim—long-headedness is the rule The prevalence of round-headedness amongst the Aschkenasim is attributed by Dr. Kappers to an early prevalence of this form of head in Mesopotamia, from which country he derives the ancestry of the Hebrews. Also he believes that the Aschkenasim, as they had to cross Anatolia on their way to Europe, may have become further contaminated by some of the round-headed peoples of Asia Minor The Sephardim, on the other hand, he supposes to be chiefly derived from the Phœnicians or Canaanitic inhabitants of Palestine, who were long-headed and presumably were darker skinned than the people of the Exodus. Because of the high degree of variability in head breadth and also in their blood affinities, Dr Kappers has inferred that the Jews are to be regarded as a religious sect rather than as a race. Here again we meet a problem which is still a matter of debate amongst anthropologists—What is a race in the modern world of humanity?

I would conclude this brief review by quoting the modest paragraph with which Dr Kappers ends his text:

"My only object is to give an introduction to the anthropology of one of the most interesting fields of ancient and modern history in a simple way, so that the reader who, like the author, is not mathematically trained, may get a general impression that, I hope, is not too far away from the truth" ARTHUR KEITH.

South African Mammals

The Mammals of South West Africa: a Biological Account of the Forms occurring in that Region. By Capt. G. C Shortridge. Vol 1. Pp xxv + 437 + 23 plates. Vol. 2. Pp. ix + 439–779 + 27 plates. (London: William Heinemann, Ltd., 1934.) 42*s*. net.

SOUTH WEST AFRICA—previous to the War German South-West Africa—is the dry and rather desolate land lying between the Cunene and the Orange Rivers on the north and south,

the Atlantic on the west and the Kalahari Desert and Bechuanaland on the east

The coastal region, known as the Namib Desert, is practically rainless and is without vegetation except along some of the dry river beds, where there is sometimes a growth of a species of wild melon, the nama, *Acanthosicyos horrida*, and occasional examples of the very remarkable *Welwitschia mirabilis* Inland from this, the land rises a few thousand feet, and the country is better watered and supports a small white population and a considerable coloured one. In this vast and desolate territory a great number of the larger game animals, formerly so abundant in the old Cape Colony and the Free State, still survive, some of them in large numbers, and it is this that gives so much interest to the present work

Capt Shortridge, who has been for many years the director of the Kaffrarian Museum at King William's Town, has made six collecting expeditions, extending over a period of ten years, to this happy hunting ground on behalf of his own Museum and the British Museum (Natural History). He has therefore had ample opportunity for acquainting himself with the ranges and habits of the mammalian fauna of South West Africa

After a short introduction on the physiography of the country, he proceeds to enumerate the mammals, commencing with the monkeys and concluding with the pangolins The nomenclature is very carefully worked out and all the numerous subspecific races are detailed, but there are no descriptions or keys, so that the work affords little help to the traveller or resident in identifying his captures The author gives us, however, a great deal of other information as regards the native names, the distribution in South West Africa and outside, and full accounts of the habits both as observed by himself and as gathered from all previous sources available In this matter he has perhaps been too meticulous It would have saved a good deal of space if he had condensed the remarks of other authors into a general statement, for much of the quoted matter is mere iteration of the same facts, and a carefully condensed narrative embodying the information available would have been more satisfactory to the reader

Among the larger mammals still surviving in considerable numbers are the Cape hartebeest, the blue wildebeest, the gemsbok, kudu and eland, but the rhinoceros is now nearly exterminated and the elephants, which were so numerous in the early days of the Swedish hunter, C J Andersson, and his successor, Eriksson, are reduced to a few hundred head in the Kaokoveld and Caprivi region in the north of the territory

The volumes are illustrated with a number of photographs The most remarkable of these were taken by Mr J Koester from the air. They show herds of zebra and antelope galloping across the plains and give a most vivid idea of their numbers There is also a series of maps showing the distribution of the more important species, and a larger general reference map The two volumes, which are published by the assistance of a grant made by the Research Grant Board of the Union of South Africa from funds provided by the Carnegie Corporation of New York, are a worthy example of book-making art and are prefaced by a short foreword by Field-Marshal Viscount Allenby

An appendix of more than a hundred pages contains a detailed series of measurements of the various mammals collected by Capt Shortridge during his several journeys in South West Africa These would have found a more suitable place in the technical papers in which the results of the expeditions were worked out, such as the *Proceedings of the Zoological Society*, where several memoirs have appeared If this space had been devoted to descriptions and keys by which the various genera and species could have been identified, the volumes would have been undoubtedly of greater use both to the systematic zoologist and also to residents and visitors to South West Africa

The two volumes, however, do contain a great deal of information about the mammals of South Africa, and will doubtless be welcomed by many sportsmen and naturalists who visit that country.

The Algæ

The Structure and Reproduction of the Algae Vol 1 *Introduction, Chlorophyceae, Xanthophyceae, Chrysophyceae, Bacillariophyceae, Cryptophyceae, Dinophyceae, Chloromonadineae, Euglenineae, Colourless Flagellata* By Prof F. E Fritsch Pp xvii+792 (Cambridge At the University Press, 1935) 30s net

ALTHOUGH work on the algæ has been very extensive during the last twenty years, there has been, during that period, a noticeable lack of accessible summaries of recent information This work should remedy the omission It is a comprehensive treatment of the morphology of the algæ and it gives impressive testimony both to the extent and variety of the recent work and also to the thoroughness and judgment of its author

The present volume deals with all groups except the red, brown and blue green algæ, which are to be treated in a succeeding volume. The general method of treatment adopted brings out very well the parallel development of similar and increasingly complex vegetative and reproductive structures in the different groups The details now available

for the Xanthophyceæ (Heterokontæ) and, to a less extent, for the Chrysophyceæ and Dinophyceæ permit a further development of this view At the same time, more flagellate types have proved to show obvious relationships with these diverse lines of development and, as a result, the Flagellata (in the old sense of the term) have almost disappeared as an independent group. Most of the forms now fall naturally into the different algal groups.

Further, the great extension of cytological work now permits a general view of cytological problems in the algæ, while, in the light of this work, the problems relating to alternation of generations can be adequately reviewed in the forms of more lowly organisation Although Prof Fritsch disclaims any attempt to deal fully with the physiology and ecology of the algæ, it will be found that the sections dealing with these topics, though brief, are both full and suggestive Moreover, because the different main groups of algæ produce parallel growth forms and very similar structures, the distinctions between these main groups are primarily and largely physiological The nature of the pigments present, the chemical structure of the wall and of the food reserves thus become of fundamental importance and are necessarily treated in detail At the same time, this peculiar feature of the algæ makes it very difficult to relate fossil forms with any certainty to any of the groups now living, and Prof Fritsch rightly stresses the need for caution in dealing with interpretations which have been advanced

This critical and well-balanced attitude is, indeed, one of the outstanding features of the book. A second feature which will strike the reader is its thoroughness Perhaps this will be only fully apparent to those who have some claim to specialised knowledge of the algæ To these, the exhaustive lists of references will be a joy, and, it may be said, probably a revelation Although the book will certainly prove extremely valuable and will be generally welcomed as a textbook of the best type, it is much more than this One may venture to predict that as a statement of principles and as a source of information, it must long remain the standard work on the subject.

Short Notices

(1) *Handbuch der Experimentalphysik.* Herausgegeben von W. Wien und F Harms Unter Mitarbeit von H Lenz Band 17, Teil 2 *Technische Akustik*, Teil 1 Pp xv + 538 44 gold marks Band 17, Teil 3. *Technische Akustik*, Teil 2 Herausgegeben von E Waetzmann Pp xi + 434. 36 gold marks (Leipzig Akademische Verlagsgesellschaft m b.H, 1933, 1934)

(2) *The Voice. its Production and Reproduction, a Treatise on Voice Training, Production and Reproduction* By Douglas Stanley and J P. Maxfield. Pp xii + 287 (New York: Pitman Publishing Corporation; London Sir Isaac Pitman and Sons, Ltd, 1933) 10s. 6d net

(3) *Acoustique.* Par Prof Adrien Foch (Collection Armand Colin · Section de physique, No 166.) Pp 210 (Paris. Armand Colin, 1934) 10 50 francs.

(1) THE first two volumes under notice, written by nearly twenty experts and forming a comprehensive survey of present-day knowledge of all applications of acoustics, show how acoustics has become largely a branch of electricity. In most experimental acoustical researches now, the pressure fluctuations of the sounds are first converted into electrical fluctuations by such devices as the microphone and the indispensable thermionic valve, and are then studied as purely electrical fluctuations. The general methods used are described in a 150-page section on methods of measurement which follows a theoretical section on the basic ideas used in technical acoustics. Greater detail is to be found in the sections on the microphone, telephone and loud speaker The propagation of sound in free space covers such applications as echo-sounding Propagation over longer distances is treated in the sections on broadcasting and long-distance telephony. Speech and hearing are treated in a section on medical acoustics. Musical instruments, broadcasting, sound recording and reproduction magnetically, by gramophone records and sound films, noise prevention and shock absorption all receive detailed treatment.

(2) The second work, dealing with voice, is a more advanced treatment than the earlier volume published as "The Science of Voice" (1929) For the new work the co-operation of J P Maxfield, known in Great Britain as joint author of the first serious treatment of gramophone acoustics, secures the accuracy of the physical treatment Maxfield's brief, but very clear, outline of methods used in sound measurement is well illustrated, and is followed by Stanley's treatment of voice-production, covering all aspects of vocal technique. The whole book is a serious contribution to a subject still full of unsolved problems. An excellent index is provided.

(3) Prof Foch's little volume, which forms one of the Collection Armand Colin, the aim of which is "Vulgariser sans abaisser", is an excellent well-balanced treatment of general acoustics. There is no English book of similar size and price which covers so wide a range and is so up-to-date, and the volume would be suitable for all university students of physics. Some of the mathematics is of an honours degree standard. To have covered so wide a range without being superficial is a remarkable achievement

(1) *Introduction à la théorie des groupes et à ses applications à la physique quantique* Par Prof. Edmond Bauer Pp ii+170 (Paris Les Presses universitaires de France, 1933) 40 francs

(2) *Microénergétique* Par Dr Pierre Bricout. Tome 1. *Introduction* Pp. vii+303 Tome 2. *Les théories et les faits* Pp iv+429. (Paris: Gauthier-Villars et Cie, 1933) 100 francs each

(3) *Statistische Mechanik auf quantentheoretischer Grundlage.* Von Prof Dr Pascual Jordan (Die Wissenschaft, herausgegeben von Prof Dr. Wilhelm Westphal, Band 87) Pp xi+112 (Braunschweig Friedr Vieweg und Sohn A.-G., 1933) 6.80 gold marks

THE three books under review are complementary to one another in so far as they cover the whole range of quantum mechanics between them

(1) M Bauer's volume deals with group theory and its applications to quantum mechanics according to the methods of J v. Neumann, H. Weyl and E Wigner The arrangement of the material is on much the same lines as in Weyl's well-known book, but the treatment is easier to follow and probably more suitable for students, the arguments being set out with the clarity so frequent in French books

(2) Dr Bricout proposes to give a complete summary, adapted to the needs of students, of the researches, both experimental and theoretical, which are the basis of the quantum theory, but group theory and its applications are excluded When we consider the difficulty of collecting together in a volume of 300 pages all the mathematics and physics required by a student as a preparation for the study of modern quantum theory, we cannot help admiring the skill with which the author has carried out his difficult task The second volume of Dr Bricout's book is devoted partly to a detailed study of the principles and methods of the various forms of the modern quantum theory and a critical comparison of them, partly to a full account of the various hypotheses put forward and the experimental facts to be explained by them

(3) The small book by Dr P Jordan is on a different plane, its object being to provide a purely quantum basis for statistical mechanics The book constitutes an original and valuable contribution to the literature of quantum statistics; no one interested in this branch of quantum theory can afford to ignore it.

Moderne Physik: Sieben Vorträge über Materie und Strahlung Von Prof Dr Max Born Ausgearbeitet von Dr Fritz Sauter Pp. vii+272 (Berlin: Julius Springer, 1933.) 19.50 gold marks.

PROF. BORN has made a very successful attempt to give a clear statement of the outstanding advances in modern physics in a form which should be intelligible even to those of modest mathematical attainments The book contains the substance of seven lectures given to various associations of electrical engineers in Berlin The essential foundations for the later chapters are set out in chapters i and ii, which give brief but sufficient accounts of the kinetic theory of gases, discharge of electricity through gases and radioactivity (including isotopes) The historical order is disregarded in the next two chapters in that the idea of wave particles is introduced before the Bohr atom is discussed The last three lectures deal with electron spin and Pauli's principle, quantum statistics and electron theory of metals, molecular structure and chemical bonds These subjects are treated with admirable clearness The illustrations and tables are particularly useful, and the book is well produced It closes with some remarks on the problems that at present confront the physicist, problems the solutions of which depend largely on successful investigations of nuclear phenomena

H. L. B.

A Key to the Stars By R. van der Riet Woolley Pp viii+143+8 plates (London, Glasgow and Bombay Blackie and Son, Ltd., 1934) 5s net

THIS elementary sketch of the more fundamental aspects of astronomy is specially designed by the author to describe "certain knowledge" or "demonstrable results which partake of the character of laws of Nature" The latest developments of astronomy in which "speculation is still rife" are deliberately excluded, though there are occasional lapses when controversial points are discussed On the whole, the author has succeeded in his object of giving the lay reader a clear outline of the methods used in astronomical research and of the more definitely ascertained facts which have been disclosed. He has been more particularly successful in describing some of the fundamental conceptions on which modern astrophysics is based, in two chapters on the temperatures and composition of the stars There might, however, have been more extensive treatment of several points without violating the expressed rule against introducing speculative matter —especially as he devotes a certain amount of attention to such subjects as stellar evolution and the rotation and expansion of the universe

Dreams in Old Norse Literature and their Affinities in Folklore With an Appendix containing the Icelandic Texts and Translations by Dr Georgia Dunham Kelchner Pp viii+154 (Cambridge At the University Press, 1935) 10s 6d net

THE material with which the author here deals is in its special field unique Not only do the dreams which she has extracted from Old Norse literature constitute the only record of its kind from among the old Teutonic peoples; but also they belong to both pagan and Christian times It is thus possible to mark the change in thought implicated by the transition from one system to another In this respect this material is probably a safer guide than the folk lore with which the author has instituted a comparison The sources from which the material is drawn are the Elder and Younger Eddas, the prose Saga and Skaldic poetry. The original Icelandic text, with translation, of a selection of the dreams is given in an appendix, and introductory chapters add a background in a brief account of early Icelandic history and culture.

Electron Diffraction as a Method of Research*

By PROF. G. P. THOMSON, F.R.S.

IN 1924, Prince Louis de Broglie put forward the thesis that all material particles, and in particular electrons, have properties analogous to those of a train of waves. This view, which is now universally accepted, is the foundation of 'wave mechanics', the modern theory of interatomic effects. It predicts that electrons should show diffraction effects with crystals similar to those given by X-rays. For the present purpose, it is a sufficient statement of the theory to say that a beam of electrons uniform in energy is regarded as replaced by a train of waves the wave-length λ of which is given by λ = (Planck's constant h)/(the momentum of an electron). As this wave train passes through matter, each atom of the matter is the source of a scattered wavelet the amplitude of which is (very roughly) proportional to the atomic number of the atom. These wavelets will interfere with one another and with the original wave exactly as the corresponding wavelets in optics, and form an interference pattern, varying in intensity from point to point, in the space behind the scattering matter. De Broglie asserted that if any detector of electrons, for example, a fluorescent screen or photographic plate, be placed in this space, the distribution of electrons recorded by it reproduces exactly the interference pattern, the electrons recording themselves in large numbers where the intensity of the waves in the pattern is large, and only sparsely where it is weak.

Calculation shows that $\lambda = 10^{-8}$ cm for electrons of 150 volts energy; it diminishes as the energy increases, being about $0{\cdot}7 \times 10^{-9}$ cm for 30,000 volts, which is the order of energy used in most of the work to be described. The wave-length is thus of the order of that of X-rays, but the scattering per atom is about 10^7 times as strong, corresponding to the far greater stopping and scattering power of matter for electrons than for X-rays.

The first test of de Broglie's hypothesis was made by Davisson and Germer[1] using slow electrons (~100 volts), although they found an agreement with theory which was rightly taken as establishing the truth of the hypothesis, there were outstanding differences from the simple theory which later experiments have rather increased than diminished. Some of these are probably due to difficulties of technique and the extreme sensitivity of slow electrons to surface impurities, others to neglect of second order effects in the theory, but until there is better agreement with theory the experiments cannot be used with safety to investigate unknown structures.

Work with cathode rays (~30,000 volts energy) is free from this objection. Experiments[2] with thin films of metals (~10^{-6} cm) showed an excellent agreement in all particulars with the theory, making use of the known crystalline structure of the metals as previously found by X-rays. Once this is established, the electron waves become a new tool to investigate the structure of matter. All that is necessary is that they should pass through the specimen to be studied without losing energy by inelastic collision, for this would alter the wave-length and destroy all phase connexion with the original wave.* The new tool closely resembles X-ray diffraction but the two are in some respects complementary in their usefulness, for while the X-rays are deep penetrating and average over a considerable volume of matter, the electrons only penetrate a shallow layer and can detect surface peculiarities which would be swamped by the excess of internal matter if X-rays were used.

A further advantage of the greater scattering is that exposure times are less. Electron diffraction patterns require seconds or less, while the corresponding times for X-rays run into hours. This is important for the investigation of gases, and promises to have considerable importance in chemistry. The diffraction pattern obtained from a gas, either with electrons or X-rays, consists of diffuse rings. It is due to interference between wavelets scattered from atoms *in the same molecule*, and the position and intensity of the rings depend mainly on the various distances between the atoms. Consequently it is possible to test stereochemical theories by comparing patterns calculated from them with those actually found. Important work has been done on these lines by Wierl[3], Brockway and Pauling[4], de Laszlo[5] and others.

Debye has used X-rays in a similar way, the theory being practically identical. As compared with the crystal method of investigating the shapes of organic molecules, there is the advantage that the molecule is studied free from its neighbours' influence, and also that the effects of molecular shape are not mixed up with those of the crystal lattice. As an example of the method, Wierl[3] was able to show that the benzene ring forms a plane hexagon, while cyclohexane is wrinkled. Again, Hendricks and others[6] showed that in 1.2 diiodobenzene the I–C valency

* Substance of a course of four lectures given at the Royal Institution on January 15, 22, 29 and February 5.

* Even so, it may be possible for interference effects to occur, but only between wavelets elastically scattered *after* the inelastic collision and originating from the same electron.

directions are bent out 10° from the symmetrical positions, thus leaving room for the normal I—I distance of 4 00 A, an example of 'steric hindrance' Considerable progress has been made with determining inter-atomic distances The table shows some of the latest results

TABLE A

Link	Aliphatic $-\overset{\vert}{\underset{\vert}{C}}-X$	Ethylenic $-C\!\!<^{X}_{X}$	Aromatic $>C-X$	Acetylenic $\equiv C-X$

C to Cl	1 76	1 74	1 69	—
C to Br	1 93	1 91	1 88	1 84
C to I	2 12	2 10	2 05	2 03

For solids which can be obtained as thin films, a very simple apparatus is sufficient All that is needed is a beam of cathode rays limited by fine holes, a holder for the film and a photographic plate which can be lowered into place without disturbing the vacuum. Fig 1 shows a typical diffraction pattern formed in this way. But the range of usefulness of the method is greatly increased if we can investigate surface layers on massive solids To do so requires a more elaborate apparatus, as it is necessary to adjust the surface to the beam by moving it in the vacuum. The adjustment has to be fairly precise, for the angles of diffraction are only of the order of 1°–5° Suitable specimens are about 1 cm. square and are carefully flatted before use. A metal specimen, if then etched, will give sharp semi-circular rings (the other half or rather more lies in the shadow of the specimen) similar to those given by a thin metallic film and characteristic of the crystal structure of the metal

The rings are due to electrons passing through minute crystalline projections on the surface If the surface is then oxidised, the pattern changes to rings characteristic of the oxide. In this way, for example, Cates[7] has shown that the surface layer of rust is γFeOOH even when the rust is black, though the bulk of the material in this case is probably Fe_3O_4. Copper[8] shows sometimes ordinary Cu_2O and sometimes another, unidentified oxide, not CuO in its usual crystalline form but perhaps an unstable modification Silver mirrors are known to be improved by holding for a short time in the fumes of aqua regia; Dixit[9] has shown that they then become covered with a layer of Ag_2O. Many other compounds have been observed as a result of chemical reactions In some cases they cannot be identified, for the evidence given by a ring pattern is like that given by an optical spectrum in that one cannot deduce the nature of the substance from the pattern or the spectrum, except by comparison with that of a known substance. If the presence of some compound is suspected, it can be tested for by comparing the pattern given by the specimen with that given by the compound, which can often be found by powdering some of the compound on to a very thin film of celluloid or similar substance transparent to electrons, which is then examined by transmission

It is a rarity to find a clean surface which does not give some sort of pattern, but to get good results the surface must be carefully prepared The chief difficulty is to reduce the 'background' due to electrons inelastically scattered Electrons will not penetrate more than a small multiple of 10^{-6} cm without an inelastic collision, but they will go hundreds of times as far before they get so slow that they fail to affect a photographic plate A good specimen is one which has relatively few lumps of thickness within this range.

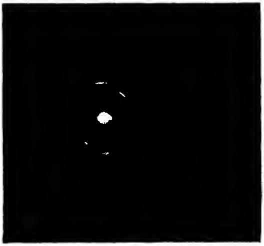

FIG 1 Diffraction pattern of gold foil (85 kilovolts)

Just as in the case of X-rays, the sharpness of the rings is a valuable indication of the size of the minute crystals causing them Small crystals give diffuse rings, being equivalent to diffraction gratings of poor resolving power In practice the diffuseness becomes marked if the crystal size is less than about 10^{-6} cm. Owing to the small angles involved in electron diffraction, there is a marked difference in the effectiveness of the rows of atoms along and perpendicular to the beam, which is important in dealing with patterns such as those given by the cleavage faces of ionic crystals and indeed by single crystals generally. Unless the thickness in the direction of the beam is greater than about 10^{-6} cm the atoms along the beam will not interfere completely, and the pattern will resemble that given by a 'crossed grating' corresponding to the array of atoms in the plane normal to the beam, rather than that given by a

three-dimensional crystal (Fig 2) Since 10^{-6} is greater than the effective penetration of the electrons, the patterns given by rough (etched) crystals are all found to be of the 'crossed grating' type On the other hand, smooth cleavage surfaces can give the X-ray type of pattern since the whole surface is bathed in each electronic wave, and interference can occur between atoms on the surface any

FIG 2 Diffraction pattern due to etched single crystal of copper

distance apart provided only that the crystal structure is perfect This last restriction is interesting because it enables one to deduce the degree of regularity of the surface from the sharpness of the diffraction pattern In some cases, for example, diamond, the structure can be shown to be regular over a distance greater than 2×10^{-6} cm , in others, for example, rocksalt, the region of regularity is less and depends greatly on the care with which the surface is prepared. There is no evidence of any inherent 'coarse structure' in crystal surfaces

Another valuable test of crystal accuracy is afforded by the Kikuchi lines , these are pairs of parallel black and white lines which often appear on the photographs when single crystals are used as specimens Kikuchi[10] showed that they are caused by repeated scattering of the electrons, and that each pair lies symmetrically on either side of the line in which some plane of the crystal intersects the plane of the photographic plate. It follows that if different parts of the crystal are inclined to one another, they will give different lines, and if there is any continuous range over which the crystal directions vary, the lines will be smudged. Actually they are often surprisingly sharp, and in such cases one can say that the orientation of the crystal is perfect to 10′ or better. The lines are often poor or absent from metallic crystals, as one might expect, since the softness of these single crystals favours distortion

An interesting modification of the theory becomes necessary when dealing with diffraction by very flat surfaces. The wave-length of the electrons depends on their momentum, and changes when they enter a region at a different potential It follows from Huygen's construction that there is a refraction of the waves at entering and leaving the surface, and a consequent shift in the position of diffracted spots For cathode rays the refractive index of most substances only differs from unity by about 1 in 5,000 but, owing to the small glancing angles used, the effect is quite appreciable provided the surface is flat It is negligible if the electrons pass through roughnesses or if the glancing angle is more than about 5°. The values found for the inner potentials of ionic crystals are of the order of 12 volts (see table B) ; this is in general agreement with the mean potential which would result from the distribution of electrons in the crystals, but no accurate calculations have so far been made It is difficult to get flat enough surfaces on metals, but Darbyshire[11] has been able to show that the inner potential of zinc is 15.5 volts and of antimony about 12 volts, values which agree roughly with what is to be expected on Sommerfeld's theory of electrons in metals

Electron diffraction seems likely to yield important information as to the process of crystallisation and the mechanism of crystal growth. For example, it is found that films of metals deposited either by cathodic spluttering or by evaporation are in the form of small crystals disposed at random on the substrate. Heating to quite a moderate temperature, far below the melting point, results in the films recrystallising in such a way that some simple crystal face is more or less parallel to the surface of the substrate[12]. In some cases the orientation is almost perfect, in others not so marked. The face chosen seems to depend mostly on the temperature[8] and not on

TABLE B INNER POTENTIALS OF IONIC CRYSTALS

Substance	Density	Yamaguti	Shinohara	Dixit	Tillman		Mean
Rocksalt	2.1	7.7	6.3		7.9[1]	6.0[2]	7.0
Zincblende	4.1	12.7			12.6	12.1	12.5

[1] Measurements with electrons of average energy 30,000 volts [2] Measurements with electrons of 8,000–5,000 volts

the nature of the substrate unless this is closely related in crystalline structure to the film Thin films of oxide lifted off the surface of molten metal often show strong orientation, usually a tetragonal or hexagonal axis, as the case may be, is normal to the plane of the film[13] Trillat[14] has observed the growth of thin films of metals into single crystals under heat treatment Kirchner[15] finds that films of salts such as cadmium iodide, when deposited on celluloid by evaporation, give diffraction patterns by transmission which show that the crystals when first formed are small, but grow on standing even at room temperature, and orientate themselves

An interesting effect has been reported by Finch[16] when a surface of polycrystalline zinc is oxidised *in vacuo* The zinc oxide, which, like the zinc itself, is hexagonal in structure, appears in a modified form in which the basal plane is constricted so as to conform in size with that of zinc, there being a corresponding extension of the hexagonal axis so that the volume of the unit cell remains approximately unchanged Presumably the oxide is formed on the basal plane of zinc crystals and tries to accommodate itself to the spacing it finds I have observed[17] a different effect with a copper single crystal, a cubic structure (probably Cu_2O) appears which conforms in *direction* with the cubic structure of the copper, but has a different spacing Interesting effects occur with oxide films on the surface of molten metals Thus Jenkins[18] has shown that these take the form of small patches of oxide orientated with a crystal axis normal to the surface but otherwise at random When the lead solidifies—under the conditions of the experiment it forms a few large crystals—the oxide patches on it turn round into parallelism forming a single thin crystal, presumably under the influence of directive forces from the crystallising metal

Researches by electron diffraction in England[18] and Germany[19] have furnished proof of the existence of the layer of amorphous material on the surface of polished metals which Sir George Beilby first discovered by microscopy. If a polycrystalline metal surface is worked with abrasives in the usual way, the rings get gradually more diffuse, indicating a reduction in crystal size, until when the surface is fully polished all that remains is two very diffuse rings. These broad rings can sometimes be regarded as due to the fusing together of groups of rings which have grown diffuse, but more often they occur in the wrong position. In these cases, and, by analogy, in the others too, one must regard them as due to a truly amorphous state of the metal. The relative size of the two rings is constant (1·85 : 1) and agrees well with that found by X-rays in liquid mercury, and with the theory of diffraction by a random aggregation of spherical atoms. From the size of the rings we can deduce the diameter of the atoms In some cases this agrees well with those found from crystal structure, in others the sizes are too small, perhaps indicating an abnormal configuration of the outer electrons Finch[20] has observed that thin layers of other metals deposited on these polished surfaces disappear after a few seconds, being apparently dissolved by the amorphous layer Only after repeated deposition of the foreign metal can a permanent layer of it be formed

A research of a very different type is that made by Murison[21] on layers of grease and other lubricants He found that long-chain carbon compounds and greases when smeared on a metal or oxide surface form a structure of molecules orientated with their lengths normal to the surface The structure is pseudo-crystalline in that these long molecules have a common direction and roughly constant distance apart between their chains, but there is no lattice The orientation indicates a strong attraction for the metal surface which prevents the grease being squeezed out of a lubricated bearing, while the absence of rigid crystal form makes it possible for the molecules to bend readily past one another and so accommodate the irregularities in the surfaces to be lubricated The lubricating effect of graphite has also been studied[22], it depends on the orientation of the flakes of graphite parallel to the surfaces

The above short and incomplete account may perhaps give an idea of the kind of problem which can usefully be attacked by the method of electron diffraction Readers may be surprised at the absence of any mention of gas layers adsorbed on solids So far no effects which can be attributed to them have been observed with fast electrons It is possible that the electronic bombardment is intense enough to remove them from the surface.

Light-Waves as Units of Length*

By DR. W. EWART WILLIAMS, King's College, London

COMPARISON OF THE RESULTS

WITH the exception of Sears and Barrell, none of the investigators seems to have realised the full implication of the fact that, while the yard or metre are purely distances, the paths observed by means of all forms of interferometers are 'optical paths', or the product of the metrical distance and the refractive index of the space concerned. The two quantities only coincide when the space is a vacuum, so that if a given standard is said to contain so many waves in air, the nature and consistency of the air must be specified to such limits that its index cannot vary by an amount greater than the percentage accuracy within which the value is specified. Not only are the temperature and pressure of importance, but almost equally so the constitution and composition of the air.

The primary importance of the work of Sears and Barrell lies not so much in the accuracy and thoroughness with which the investigation has been carried out, as in the fact that they have provided us with the vacuum wave-length of the red cadmium line, carrying out a direct comparison with evacuated units as well as with air. It is very disquieting to find that the refractive index of air thus accurately observed is considerably different from that given by the Meggers and Peters tables[19], which is the standard conversion table in general use by spectroscopists for obtaining the vacuum frequencies of spectral lines.

The humidity of the air was not observed in the earlier work of Michelson; at 15° C. the index increases by 7 parts in 10^7 when saturated air is replaced by dry air. If we assume the air to have had an average humidity of 50 per cent, Michelson's value for the wave-length must be reduced by 0·0023 A. to obtain the result for dry air.

Neither Michelson, nor Benoit, Fabry and Perot, took account of the percentage of carbon dioxide present during their experiment. Normal 'fresh air' is supposed to contain 0·03 per cent carbon dioxide, but the amount present in a closed room may be far in excess of this due to the presence of observers. Pérard[20] has shown that an observer will contribute approximately this amount to the air of a room of 100 cubic metres capacity in the time required for a single set of observations, namely, 1½ hours. An increase of 0·03 per cent in the carbon dioxide content decreases the wave-length by 0·0003 A., so that only the more recent determinations can with strict fairness be intercompared.

* *Continued from p.* 461.

The values of the wave-length of the red cadmium line in dry air containing 0·03 per cent carbon dioxide at 760 mm. pressure and 15° on the normal temperature scale are given below:

Standard No	Year	Investigators	Value in 10^{-10} metres
*26 and T_3	1906	Benoit, Fabry, Perot	6438·4703
10 and 20	1928	Watanabe and Imaizumi	6438·4682
16	1933	Sears and Barrell	6438·4708
18	1934	Kösters	6438·4672
		Mean	6438·4687

* The results have been corrected in terms of the more recent determinations of the lengths of these International Sub-standards.

For the present, this is probably the best value that can be taken for the wave-length of this line in 'normal' air. It differs but little from the accepted value of 6438·4696 A., which was primarily based on the determination of Benoit and his co-workers. The difference of 0·0036 A. between the values of the Reichanstalt and the National Physical Laboratory seems far too great, since it amounts to almost a whole wave-length in the number of waves in the metre. The discrepancy has most probably arisen in the initial comparison of the national standards with the Sèvres sub-standards. The preliminary Japanese results showed a difference of 0·002 A. between the values obtained from the two standards No. 10 and No. 20. These were later sent to Paris for re-measurement against the international sub-standard No. 26 and others. The corrections of + 0·2 μ for No. 10 and − 0·11 μ for No. 20 brought the wave-length values into close agreement. The result of Benoit and his co-workers has been included in the above table in spite of the uncertainty regarding the carbon dioxide content. The probability is that the lengths of No. 26 and T_3 are more accurately known than those of the National Standards, and the greatest source of error undoubtedly lies in this portion.

It seems imperative that the rule prohibiting the actual use of the prototype metre itself will have to be waived, and the German and British standards be compared with it as soon as possible. The difficulty of this work can best be appreciated from Fig. 1. This photograph (reproduced by courtesy of M. Pérard) shows, with a magnification of 300, one of the fiduciary lines of the International Sub-standard No. 26 which has been used in the earlier determinations. The centre of the whole is supposed to be the actual position of setting, and metrologists claim that they can intercompare two standards to within ± 0·2 μ. This is equivalent to finding the centre of Fig. 1 to within ± 0·03 mm., which is clearly impossible. By

reducing the magnification a sharp image is obtained, which is more of the diffraction pattern of the comparator objective than an image of the actual line itself. The result in a great measure will then depend on the conditions of illumination of the line comparator

It seems certain that minor systematic errors, in the optical portion, chiefly connected with the conditions of illumination of the étalons, still remain uncorrected Their effects are, however, negligible compared with the real uncertainties of line standard measurements Even at the present time, there would be a considerable gain in accuracy if a wave-length were accepted as the fundamental standard, but before a change is decided upon, it seems very desirable that the whole position should be reconsidered in the light of recent knowledge The discovery of the hollow cathode discharge by Paschen and its further development by Schuler have given us a light source that is much more monochromatic than the Geissler tube of Michelson or the argon-filled cadmium lamp as used by Sears and Barrell The further possibility now exists of finding a more suitable line from a heavier, non-isotopic element of zero nuclear spin, since we are no longer limited to the more volatile elements

Tilton[21] has recently carried out a statistical analysis of the data on the refractive index of carbon dioxide-free air, from which he deduces a correlation between the refractivity ($\mu - 1$) and the twenty-three year magnetic cycle of sunspots Some of the data are admittedly uncertain, but there seems to be evidence of a real variation that makes it essential to adopt a vacuum wave-length as the ultimate standard, if and when a change is made

For the moment, we cannot do better than accept the mean value given in the above table as the wave-length of the red cadmium line in

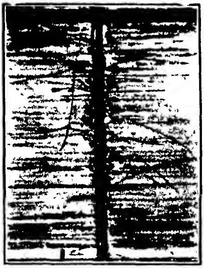

FIG 1 One of the fiduciary lines of the International sub-standard No 26 (×300)

'normal' air, and to adopt Sears and Barrell's value, 1 000,276,49, as its refractive index The vacuum wave-length then becomes 6440·2493 A and the Imperial yard, defined as a length at 62° F, contains 1,419,818 31 vacuum wave-lengths.

Obituary

PROF. BOHUSLAV BRAUNER

PROF. BOHUSLAV BRAUNER, one of the best-known representatives of Czech chemistry of the last half century, died in Prague on February 15, after a short illness He was born on May 8, 1855, in Prague, the son of Dr Francis Brauner, who was a noted Prague lawyer and Czech political leader His mother Augusta, a very talented and spirited lady, was the daughter of Prof K A Neumann, the first professor of chemistry at the Polytechnic Institute of Prague, and the grand-niece of the well-known German pharmacist, Prof. Caspar Neumann (1683–1737), one of the founders of pharmaceutical chemistry.

Thus Brauner seems to have inherited his liking and ability for chemistry from his mother's side. Great attention was paid in the Brauner family to languages, amongst which besides the Czech mother-tongue, Russian, English, German and French were equally cultivated. There the foundation was laid of Brauner's astonishing practical linguistic knowledge. He showed a refined taste for fine arts like the other members of his family, his sister Zdenka Braunerová being a well-known Czech painter

In 1873, Brauner went to the University and to the Technical School in Prague, where one of his teachers was the physicist Ernst Mach, at that time professor in the University of Prague Before attaining the doctor's degree, young Brauner went abroad for training in research, contrary to the fashion at that time, when "every chemist had to embark on organic chemistry", he preferred inorganic training under Bunsen in Heidelberg in 1878 Two years later, Brauner went to Manchester, attracted by the work of Sir Henry Roscoe on rare elements.

The school of chemistry in Owens College, Manchester, had a profound influence upon Brauner, who learned there to love the original Anglo Saxon spirit of experimental investigation in natural philosophy. During his years in Manchester, Brauner was eagerly investigating the rare earths, and he succeeded in preparing a double fluoride of tetravalent cerium and potassium which on gentle heating gave off free fluorine, thus for the first time obtained

by purely chemical means. Fourteen years later, he found a similar reaction with lead tetrafluoride

Fascinated with Mendeléeff's system, Brauner entered into scientific correspondence with the genial Russian chemist in 1881 and was greatly impressed by meeting him in St Petersburg There a cordial friendship between the two enthusiastic Slavonic chemists began, to last for twenty-five years, until the death of Mendeléeff

A problem which occupied Brauner's mind for a long time was the position of the rare earth elements in the Periodic System. As a strong adherent of the tabular form of the system, he expected that these elements would somehow fit in so as to show their chemical analogies By determining carefully their atomic weights, he was already able to predict the gap between neodymium and samarium. In his investigations at Manchester, Braunor succeeded in showing the complexity of didymium, denoting by Diα and Diβ what Auer von Welsbach three years later called praseodymium and neodymium This brilliant work was submitted by Brauner to the Charles University of Prague for his 'habilitation' thesis He was appointed assistant professor there in 1890 and full professor in 1897

During his whole academic career, Prof. Brauner worked intensively at the chemistry of the rare earths and on the determination of atomic weights As a specialist in the first branch, he was asked by Mendeléeff to write the account on rare earths in his famous textbook "Principles of Chemistry", whilst in the other branch he immortalised himself in Abegg's well-known "Handbuch der anorganischen Chemie", to which he contributed his masterly critical discussion on atomic weights. As an authority on those determinations, he fought, together with Venable, for the new base O = 16·000, right down to its general adoption at the Paris Congress in 1900.

Prof. Brauner retired in 1925, after forty-three years of teaching, during which time he lectured to generations of chemists and pharmacists. The highest scientific distinctions came to him not only from his own people, but still more so from abroad. Those he treasured most were the honorary memberships of the Chemical Society of London, the American Chemical Society and the Société Chimique de France, and the honorary D.Sc of the University of Manchester. His seventieth birthday was celebrated by a jubilee number of the *Recueil des Travaux Chimiques des Pays-Bas* in 1925, and his seventy-fifth birthday by the jubilee number of the *Collection of Czechoslovak Chemical Communications* in 1930.

The personality of Prof. Brauner was one of imposing and original individuality His Herculean figure, quick penetrating eyes, high and broad forehead, and strong features harmonised well with his commanding voice, dry remarks and sarcastic wit Yet his sanguine enthusiasm often also brought tears into his eyes, revealing his gentleness of heart and love for mankind and the whole of Nature One of his great hobbies was astronomy, the progress of which he followed as eagerly as that of chemistry. No wonder that with such naturalistic bent he soon became a passionate and ardent reader of NATURE, of which he had read carefully every number, starting from his Manchester days in 1882 Often he contributed to it thoughtful and conscientious reports His recreation was sport, which he introduced and promoted enthusiastically in Bohemia, having become attached to it during his studies in England His Spartan mode of life most probably preserved his health in spite of the noxious atmosphere of the chemical laboratory and his somewhat delicate lungs Yet pneumonia, which attacked him several times in his stronger days, succeeded at last in overcoming him in his eightieth year, to the sincere regret of his two sons and daughter and his many devoted friends and pupils

J. H

SIR LESLIE MACKENZIE

WE regret to record the death of Sir William Leslie Mackenzie, which occurred in Edinburgh on February 28

Sir Leslie Mackenzie was a native of Ross-shire and graduated M A, with double honours, at the University of Aberdeen in 1882. He studied medicine in Aberdeen and Edinburgh and, at the latter University, took the degree of M.B, C.M., with honours, in 1888, and M.D, with highest honours, in 1895 He held the D P H and was a fellow of the Royal College of Physicians of Edinburgh In addition to achieving a brilliant career in medicine, Sir Leslie was a recognised authority on psychology and mental philosophy. He had gained the Fullerton and Ferguson scholarships in mental philosophy, and was at one time examiner in mental philosophy as well as in medical jurisprudence and public health at the University of Aberdeen. His later work was recognised in the award of the Medal of Honour of the University of Brussels in 1920. In Aberdeen also he was a resident medical officer in the Royal Infirmary and afterwards was assistant professor of physiology and Arnott lecturer in physiology at Gordons Colleges. In his earlier work he had thus a wide knowledge and interest, as well as considerable and diverse experience.

For Sir Leslie's later work, which was more of a public nature and had its outcome in the development of the various modern branches of public health service during his term of office on the Local Government Board and Scottish Board of Health, he had his first insight while, for a time, assistant to that eminent and widely-known hygienist, Prof. Matthew Hay, medical officer of health for the City of Aberdeen. From this assistantship he became the first medical officer of health for the combined counties of Wigtown and Kirkcudbright, under the Local Government (Scotland) Act, 1889, where he had to organise the public health work of a very large area He and Prof. Hay were selected to give evidence before the Royal Commission (for Scotland) on physical training. He had carried out for the Commission and reported on the examination of six hundred school children, and the Commission's report resulted in the establishment of the School Medical Service.

In 1894, Sir Leslie was appointed medical officer

of health for Leith, where his ability and achievements, added to those already accomplished in his previous appointments, led to his selection, in 1901, for the post of medical inspector under the Local Government Board for Scotland. In 1904, he became medical member of the Local Government Board and later of the Scottish Board of Health which took its place In the latter capacities he took a prominent part in the development of the tuberculosis service and the scheme for medical services in the Highlands and Islands of Scotland His name is also closely associated with the development of the maternity and child welfare service, he having, in 1915, prepared a report for the Carnegie Trust on "Scottish Mothers and Children", published in 1917 At this time also he was a member of the Royal Commission on Housing, the Ballantyne Commission, a branch of public health work which he himself regarded as among the most important, if not the most important, of his activities for the betterment of the people of Scotland. He was also crown nominee for Scotland on the General Medical Council.

Among Sir Leslie's published writings, other than those already referred to, were "The Nervous System" in Prof Bain's "Senses and Intellect", "The Development and Outlook of Public Health" in Nelson's Loose Leaf Medicine, "Health and Disease", "The Health of the School Child"; "The Medical Inspection of School Children"

The sympathy of all who knew him, personally or by repute, will go out to Lady Mackenzie, who also is a well known and active social worker. Lady Mackenzie has taken a keen interest and no small part in the effort for the improvement of conditions in Scotland, and is a member of several boards of public bodies and of the Departmental Committee now receiving evidence on the health services of Scotland

News and Views

'Backward Tribes' in the India Bill

COL WEDGWOOD, by moving two amendments on Clause 91 of the India Bill in the House of Commons on March 22, secured from Sir Samuel Hoare a statement of the intentions of the Government in dealing with the primitive tribes of India He pointed out the extreme undesirability of the probable course of action of the Provincial Governments in an effort to assimilate tribal areas to conditions in the rest of the territory under their jurisdiction, and urged the retention of such areas under British control with a system of administration similar to that of 'indirect rule' which has been introduced in West Africa. That the problem is by no means negligible in its dimensions is indicated by the numbers affected Col. Wedgwood's estimate puts the numbers of the backward tribes at 43,000,000, of whom 13,000,000 only will be affected by the protective measures proposed by the Government. These figures are in excess of those given in the Census Report of 1931, where the primitive tribes are stated to number 25,000,000 (in round numbers), of whom 8,280,000 are said to retain their tribal religion. The difference is probably due to the more rigid exclusion in the Census figures of tribes which have passed over recently, or are in process of passing, into the depressed classes, the usual fate of tribes which have come into contact with outside conditions.

ALL observers are agreed as to the delicate equilibrium of the social organisation of the primitive tribes of India, which is unable to withstand even the most impartial application of the principles of British justice In Rajputana, for example, it has been found to have led, in the desire to distribute even-handed treatment, by almost imperceptible degrees to an increase in the power of the land-owner and the restriction of the rights of the tribal holding Any increase in facilities of communication has had a rapidly disintegrating effect. Sir Samuel Hoare was able to give the House an assurance that the Government has this aspect of the matter in view, and he informed the members that, as the result of consultation with expert opinion in India, it had been decided that certain areas, wherever such treatment was possible, would be scheduled for control by the Governor only He closed with the confident statement that "the Government had made the position safe". In so doing, he appeared to rely to a great extent upon the fact that there has developed a school of Indian administrators "who had specially concentrated on the study of the kind of problem that was in the mind of Col Wedgwood" Some assurance, however, that measures are being taken to ensure that the supply of such administrators will not fail in the changed conditions would have been even more welcome.

Antiquities in Iraq

FURTHER details of the allocation of antiquities from Ur as between the Bagdad Museum and the institutions which were responsible for the Joint Expedition are given by Dr. Leonard Woolley in *Antiquity* of March. These, unfortunately, had to be omitted from his communication in *The Times* (see NATURE, 134, 999, 1934); but they should convince any impartial judge of the fairness of Dr. Woolley's contention that the principle of division has operated in favour of the Bagdad Museum, and that there is no ground for the accusation that Iraq has received a negligible proportion of the finds or has been deprived of priceless treasures which should not have left the country Dr. Woolley admits that in the earlier years of the excavations objects of exceptional importance or value were allotted to the share of the Expedition; but this was due to the fact that the Bagdad Museum had not then the technical equipment necessary for their special treatment and preservation. As Dr Woolley's statement is precise, its detail is open to verification; but a reply which

has since appeared in the Bagdad paper *el Bilad* evades this issue Dr Woolley goes on to show specifically in detail that the Antiquities Department of Iraq, having first choice, was in a position to, and did, select the most valuable and finest specimens for its proportion of the finds, without any compensation being given to the Expedition The law is interpreted in such a way that there is a danger that the share of any Expedition may become insufficient to justify the expenditure entailed by the work of excavation The reduction of the number of expeditions in this field to three indicates that this view is only too well founded.

Artificial Lighting at the National Gallery

ON and after April 1 the public will be able to visit the National Gallery, Trafalgar Square, until 8 p m on three evenings in the week This has been made possible by a new lighting scheme, which has been the subject of extensive research during the past six years The installation has been designed to secure a reasonably high intensity—about 4 foot-candles—upon the pictures themselves, and at the same time to prevent too great a feeling of darkness over the remainder of the room Suspended fittings, each containing a high powered frosted bulb, are used, and a system of louvers and reflectors directs as much light towards the picture carrying portion of the walls as the architecture of the several rooms will permit. The height of the fittings has been calculated upon the assumption of a viewing distance of eleven feet from the walls Masks are employed to stop the glare in the direction of doorways in the majority of cases this has proved satisfactory, though instances will always arise when the geometry cannot be satisfied without producing a shadow on the wall or in a corner An emergency system of lighting, which comes into operation automatically in case of failure, is held in reserve

International Vitamin Standards

THE International Standards for vitamins A, B_1, C and D are now available for issue to laboratories, institutions and research workers in Great Britain and Northern Ireland These standards were accepted for international use at the Second International Conference on Vitamin Standardisation held in London in June 1934 under the auspices of the Permanent Commission on Biological Standardisation of the Health Organisation of the League of Nations The Conference recommended that they should be kept at the National Institute for Medical Research, Hampstead, N W 3, which would act for this purpose as the central laboratory on behalf of the Health Organisation of the League of Nations The standards for the vitamins B_1 and D remain unchanged, and their supply at regular half yearly intervals will be continued as before The standard for vitamin A has been changed; a pure specimen of β-carotene having been adopted in place of the impure preparation of carotene hitherto employed The unit of vitamin A remains unchanged, though it is now defined as the vitamin A activity contained in 0·6 microgram of pure β-carotene In accordance with the recommendations of the Conference, the β-carotene is issued in the form of a solution in oil, of which 1 gm contains 500 international units The quantity of this standard solution supplied to each applicant is approximately 5 gm, and, on account of the small quantity available, it can be supplied only at yearly intervals, and not half-yearly as formerly. *l*-Ascorbic acid has been adopted as the international standard for vitamin C, the unit of activity being defined as the vitamin C activity contained in 0·05 mgm of pure *l*-ascorbic acid A fuller account of the recommendations of the Conference on Vitamin Standardisation appears elsewhere in this issue (p 516)

Chemical Engineering in Industry

GREAT BRITAIN is awakening to the importance of the chemical engineer, a man who knows the nature and properties of the new constructional materials or is able to design large plants for the continuous production of those materials which are classed as chemicals It is at least likely that the big developments in the future will be among the chemical industries making, at a low price, substances for which there is a considerable need, almost automatically as a continuous process Such will require the ablest chemical engineers to design and operate them There are two societies active in promoting the subject and in bringing together those who practise it, and post-graduate courses are provided in several of the London colleges Greater progress in chemical engineering has been made abroad, particularly in the United States and in Germany, and for some time past the desirability of holding an international congress has been realised by those interested, in particular by the late Sir Frederic Nathan Thanks to the assistance of the World Power Conference with its widespread organisation, a Congress has now been arranged, to take place in London on June 22–27, 1936 The programme, which has just been issued, lists the influential members of the organising committees, whose names are a guarantee of the support the Congress is receiving It further indicates the scope of the projected programme . this covers plant, fuel and heat and general problems, administration, development and general aspects of the subject It is desired that the papers, while adhering strictly to chemical engineering, should deal as fully as possible with the economic aspect of the subject The Committee aims at inviting technicians of repute to present papers dealing with particular aspects of these subjects rather than having a miscellaneous collection of papers, and if they are successful the Congress should be a memorable one

Dr. William Derham, F.R.S. (1657–1735)

ON April 5, the bicentenary occurs of the death of Dr William Derham, rector of Upminster, Essex, and for thirty-three years a fellow of the Royal Society. Born at Stoughton, near Worcester, on November 26, 1657, he entered Trinity College,

Cambridge, in 1675 and took holy orders. In 1682 he was made vicar of Wargrave, Berkshire, but seven years later was appointed to Upminster, where he spent the remainder of his life and where he is buried Derham united a sincere devotion to his calling with a passion for mathematical and philosophical studies Elected a fellow of the Royal Society in 1702, he contributed papers to the *Philosophical Transactions* on the motion of the pendulum in a vacuum, on sound, sunspots, Jupiter's satellites, the aurora borealis and other subjects His separate writings included his "Physico-theology", 1713; and his "Astro-theology", 1715, while in 1726 he edited "The Philosophical Experiments of Robert Hooke and other Virtuosoes" He was made a canon of Windsor, and in 1730 the University of Oxford conferred upon him the degree of D.D for his services in the cause of religion by his culture of natural philosophy

Lead Mining in the Northern Pennines

THE history of lead mining in the Tyne, Wear and Tees areas during the eighteenth and nineteenth centuries was described by Dr. A Raistrick before the Durham Philosophical Society on March 15. Two companies have worked practically all the mines in these areas, the London Lead Co and the Beaumonts. The former began with a charter granted in 1692 to a company formed in Bristol to attempt the smelting of ore with coal This venture closed after two years, but two Quakers, Edward Wright and John Haddon, of London, obtained the reversion of a much older charter (of 1654) of the Society of Mines Royal (Copper), a German concern formed to work Cumbrian ores Wright seems to have invented the reverberatory furnace, long called the cupola from its shape, and found that it was very suitable for lead refining They extracted silver, and with some Newcastle Quakers founded a smelt mill at Ryton-on-Tyne in 1704, before that (from 1696), difficulties with the oath it contained prevented their taking up the 1692 charter, but these were overcome in 1704, when the accumulated silver was sold to the mint. This company, long known as the "Quaker Lead Company", until 1730 had an output of about 150 oz. of silver a week, and in 1705, Sir Isaac Newton then being Master of the Mint, they were granted a mark which appears on most of Queen Anne's coinage until 1737. The maundy money was coined from their silver for another hundred years They bought ore from Alston Moor, and worked lead also in Flintshire, and finally in Yorkshire, Scotland, Ireland and the Isle of Man. The tale is too long to repeat here, but the Pattinson process of desilverisation was discovered at Blaydon in the Beaumont works. The two concerns worked harmoniously together, and many improvements were made by the London Lead Co. In 1860, the decline set in, the company surrendered all its leases in 1907; and now only three mines are working under the new Weardale Lead Co., and those recently closed will never re-open. An interested visitor at the lecture was the last manager of the old company.

Speed in Aviation

IN his Friday evening discourse delivered at the Royal Institution on Friday, March 22, Prof. B. Melvill Jones discussed the problems of speed. The speed of aerial transport is limited solely by the power which can be provided to drag the aeroplane through the air, without reference to its support; the power required increases very rapidly with speed, but can be much reduced by good stream-lining The recent increases in speed of civil air transport are due mainly to improved stream-lining With well stream-lined aeroplanes the power is expended mainly in overcoming skin friction, so that the detailed study of the skin friction on the curved surfaces of the wings and body merits, and is receiving, great attention by research workers The magnitude of the skin friction force is delicately dependent on surface smoothness and on the smoothness or otherwise of the flow very close to the surface of the wings and body. After perfect stream-lining, in the ordinary sense, has been achieved, still further important increases in speed would follow from any considerable extension of the area over which the flow remains smooth very near to the surfaces of the wings and body, but to obtain this smooth flow over large surfaces moving at high speeds may be very difficult, and it is still a matter for conjecture how much of the great increase of speed which might conceivably be obtained in this way will ever be realised in practice.

Recent Acquisitions of the Natural History Museum

THE Department of Entomology has received from Mr R W Lloyd a gift of drawings of quite exceptional interest and value These consist of the original coloured plates prepared by Jacob Hubner for his "Collection of European Butterflies", published during the years 1796–1830, at Augsburg in Germany. There are 852 plates in all, a number which exceeds that of the published work by many cancelled and amended copies Concerning the identity of some of the smaller insects illustrated there has long been doubt, it is hoped the comparisons which it will now be possible to make between the originals of these figures and the material available in this Department will enable most of these doubts to be removed It is interesting to note that until a few weeks ago it was unknown in Great Britain that these drawings even existed The Department of Geology has recently acquired from Dr. Wyatt Wingrave a large collection of fossil invertebrates (chiefly Ammonites) from the Lias and Inferior Oolite of the Dorset district A crystal of gem olivine (peridot) from Burma has been purchased for the Department of Minerals Presents to the Department include a fine group of large crystals of wolframite from Pelagatos Mountains, Peru, collected by the late Prof J. W Gregory and presented by Mrs. Gregory.

THE Department of Botany has received a collection of dried plants made in Twaong (Tibet) and Bhutan by Messrs G. Sherriff and F. Ludlow There are 523 flowering plants and 53 cryptogams, which are

specially dried and preserved, and form a most valuable addition to the herbarium, for few plants have previously been collected from this area They have not yet been wholly worked over, but it is probable that they contain a percentage of new species which will be of horticultural interest Seeds of a number of plants likely to prove of horticultural value have been sent and distributed to the more important gardens in the country. The Maharajah of Bhutan kindly granted permission for this expedition to remain longer in the country than originally arranged, and thus enabled collections to be made after the rains were over, which had not been possible in the previous season Miss Gulielma Lister has presented the 221 original drawings of the "Lister monograph" on Mycetozoa published by the British Museum The drawings are of considerable artistic beauty and scientific accuracy

Marine Biology in Ceylon

MR A H. MALPAS, acting marine biologist to the Department of Fisheries, in his Administrative Report (Marine Biology) for the year 1933 (Ceylon, Part 4 Education, Science and Art (G), April 1934, Ceylon Government Press, Colombo) expresses his regret at the severe loss the fisheries research in Ceylon has sustained by the departure on leave, preparatory to retirement, of Dr Joseph Pearson, who has done so much for the fisheries, especially the fish resources of Ceylon The survey of the pearl banks in 1933 revealed a promising sign of repopulation of the banks, small branches of oysters being found over most of the paar areas, especially over the West Cheval, usually the first paar to receive spatfall after a long period of barrenness. These oysters are not themselves of any fishable value, but are important as they may produce subsequent spatfalls to repopulate the banks. It is anticipated that a considerable area will be covered with spat at the next inspection Favourable prospects are also shown for a series of fisheries of the window-pane oyster Experiments were conducted with the view of ascertaining the effects on pearl oysters of abrupt changes of salinity It was found that oysters kept in a mixture of 1 part of fresh water to 2 parts of sea water were unaffected after several days, while others kept in a mixture of equal parts of fresh-water and sea-water quickly succumbed Although the experiments are not conclusive they indicate that, as the pearl banks are some miles distant from land, it is not possible for flood-water to bring about such a reduction in salinity as would be harmful to the pearl oysters

Survey of Salmon and Freshwater Fisheries

PROBLEMS of biological interest are raised in the Ministry of Agriculture and Fisheries Report on the Salmon and Freshwater Fisheries for the year 1933 In at least three rivers, the Wye, the Severn and the Exe, there have been reports that the size and number of smolt shoals migrating seawards in 1933 were well above the average. It is considered that the great majority of these will have arisen from the 1930 spawning, and that year was noteworthy as one in which the number of fish observed on the spawning beds was unusually low. Under such conditions the eggs will have been relatively undisturbed and well distributed. The possibility arises therefore that the presence of too many fish on the spawning beds may be detrimental by causing disturbance of the already spawned eggs and overcrowding of the newly hatched fry The production of good broods in years when the breeding stock does not appear to be large has also been observed among some sea fish. A further problem of considerable interest is afforded by the occurrence in 1933 of spring-run salmon in the River Plym, where spring fish are not normally found. Their occurrence follows on the introduction of salmon fry from eggs of early running Scottish fish in 1928 If this is an indication that such fish breed true, always producing spring fish, the results of experiments to eradicate the autumn fish running up after the close season will be watched with interest. Although in the year under review there had been a slight decline in the total catch of salmon and migrating trout, the reported mortality of fish as a result of pollution or from furunculosis has fortunately been low in spite of the dry weather conditions Much work of interest and value is being conducted at the Alresford Experimental Station from the chemical, botanical and zoological points of view, and the usual surveys of a large number of rivers have been made.

Balance of Life in National Parks

THE institution of animal reserves, on a large or small scale, eventually raises a question as to whether artificial control of conditions should be encouraged or abolished Everyone will agree with the dictum that the object is "to preserve National Park areas in as nearly as possible their natural condition and at the same time to make them accessible to the people for study, for recreation, and for play" Dr Joseph Grinnell quotes with approval, and suggests (in a short article in the *Journal of the Society for the Preservation of the Empire*, Jan 1935, p. 61) that animal life in national parks should simply be left alone "It can be encouraged in amount and variety most practically by desisting from any avoidable interference with the full range of natural conditions of food and shelter A *do-nothing* policy *is* the soundest policy. . . . Also introduction of non-native kinds of animals should be guarded against like the plague." In general, Dr Grinnell is correct, but the guardian of reserves, especially of those on a small scale, must be on the alert to correct any tendency to extremes in the population. The reason is that no reserve is a thoroughly 'natural area'; it has somewhere a boundary, and at the boundary natural migrations are checked, and unnatural slaughter takes place which rebounds upon the reserve population.

Quality of Wheat

THE quality of wheat as influenced by environment is the subject of a recent paper by F. T. Shutt and S. N. Hamilton (*Emp. J. Exp. Agric.*, 2, p. 119). The question is not one of scientific interest only, but also of the first commercial importance in the flour-

milling and baking industries Value in wheat depends chiefly on the character and amount of the protein (gluten) it contains, but whereas the former is essentially an inherited factor, the latter may be considerably influenced by environmental conditions The time which elapses between the formation and ripening of the kernel practically controls its gluten content—the shorter the period the higher the percentage—so that seasonal conditions such as high temperatures and absence of excessive moisture during the later stages of development, which tend to hasten ripening, result in a valuable high-protein wheat Conversely, a starchy grain is produced if climatic conditions tend to prolong growth during this period. The richness of the soil, even as regards its nitrogen content, does not appear to have much influence on the quantity of protein in the grain, but its moisture absorbing capacity may be of considerable importance as it is necessarily closely associated with the rate of ripening of the crop From data which have been collected over a period of twenty-eight years at a number of stations in Canada, it has been deduced that the excellent quality of the wheats from the prairie provinces is largely to be attributed to the favourable seasonal conditions that obtain, and not solely to the selection of the most suitable varieties for that district

Forest Products Research

THE annual report of the Forest Products Research Board with the report of the Director of the Forest Products Research Laboratory, Princes Risborough, for the year 1933 has recently been published (London: H M. Stationery Office 1934). In a general statement, the Director notes that the progress of timber research has been satisfactory, whether regarded from the point of view of the actual results achieved or from the value of the results when applied in the timber-using industries and professions. Sir Ralph Pearson retired from the post of director during the year, and Mr. W. A. Robertson, late of the Indian Forest Service, was appointed The report states that there is evidence of the increasing interest taken by industry in the activities of the Laboratory. The work carried out during the year on seasoning of timber, both kiln and air-seasoning, on steam bending, the structure and mechanical strength of wood and on preservation, is summarised As a result of investigation work, it is stated that "there is no material difference between old and new timbers from the point of view of shrinkage and expansion", thereby disproving a common belief. Investigations were carried on in connexion with dry rot and insect damage. Tests were also carried out on the cricket bat willow.

Birefringence of 'Viscacelle'

DR. N. H. HARTSHORNE, of University College, Swansea, writes: "With reference to my letter on the birefringence of 'Viscacelle' in the issue of NATURE of February 16 (p. 269), my attention has been directed to a note on the birefringence of 'Cellophane' contributed by Mr. Arthur M. Grundy to *Watson's Microscope Record* in 1931 (Sept, p 22) The name 'Cellophane' is commonly, though mistakenly, used as a general term for artificial cellulose sheet, and as Mr Grundy did not state the source of his material, I am uncertain as to its exact nature It was, however, doubtless very similar to, if not identical with 'Viscacelle' He noted the uniformity of its optical character, and the fact that specimens of different thicknesses gave appropriately different polarisation colours, but he gave no data for the relative retardations associated with different thicknesses He expressed the view that the optical uniformity of the material ruled out stress as a cause of its double refraction As regards 'Viscacelle', I do not think that the double refraction is due in any degree to stress in the finished material, but, as I indicated in my letter, the stress involved in the spinning process (that is while the material is being drawn from the spinning slot into the coagulating bath) almost certainly causes an orientation of the cellulose molecules, and this accounts for the observed direction of 'slow' vibration I regret that I did not see Mr Grundy's note earlier, and I gladly acknowledge his prior discovery of the double refraction of artificial cellulose sheet."

Native Chinese Drugs of Animal Origin

REMEDIES derived from the animal kingdom bulk large in the old Chinese literature, and three instalments dealing with this Chinese materia medica, compiled by Mr Bernard E Read, assisted by Chinese scholars, have been published by the *Peking Natural History Bulletin* The first instalment, containing the 'animal drugs', and the second the 'avian drugs', were issued some time ago, and now the third dealing with 'dragon and snake drugs' has been published ("Chinese Materia Medica" 7 "Dragon and Snake Drugs". By Bernard E Read Pp 66+6 plates Peiping The French Bookstore, 1934 1.50 dollars) Besides products derived from snakes, crocodiles, lizards and others, preparations from the fossilised bones of gigantic extinct saurians are included Attempts are made to identify the creatures mentioned in the old works, and a Chinese index is appended The whole forms a scholarly work of considerable interest and importance

British Mosquitoes

A REVISED second edition of the pamphlet entitled "British Mosquitoes and their Control", Economic Series 4A, published by the British Museum (Natural History), has recently appeared. The authors, Messrs. F W. Edwards and S P James, describe the characters and the habits of the twenty-eight species of these insects found in Britain Measures for the control of mosquitoes and their larvæ are also described, together with means of protection against bites of the insects The object of the pamphlet is to assist medical officers and others engaged in mosquito control with up-to-date information. It is obtainable, price 4*d*, from the British Museum (Natural History), Cromwell Road, London, S W.7, or through booksellers.

The Sky in April

THE major planets are moving round towards positions favourable for evening observation In the middle of the summer we shall see Venus, Mars, Jupiter and Saturn in the evening sky. At present, Venus is very conspicuous in the western sky just after sunset, while Mars becomes conspicuous in the eastern sky a little later In April, Mars will precede Spica, near which star it has been during March This planet is in opposition on April 6 Jupiter follows Mars, about two hours behind in right ascension, but its declination is about 17° S in April Saturn is still an early morning object. The moon will occult the Pleiades on April 6 The elements of the occultations visible at Greenwich being as follows .

Star	Magnitude	Phenomenon	G M T
η Tauri	3 0	Disappearance at dark limb	18^h 50^m
η Tauri	3 0	Reappearance at bright limb	19 19
27 Tauri	3·8	Disappearance at dark limb	19 24
28 Tauri	5 2	Disappearance at dark limb	19 37

On the early morning of April 22, the moon will occult Antares, magnitude 1 2 The reappearance of this star at the dark limb will be visible at Greenwich and will take place at 1^h05^m G M T

Announcements

A DISCUSSION on "Gravity Measurements" will be held in the rooms of the Royal Astronomical Society, Burlington House, London, W 1, on April 26 at 4 30. The discussion will be opened by Dr E C Bullard.

THE Triennial Gold Medal of the Royal Asiatic Society has been awarded to Sir Denison Ross, director of the School of Oriental Studies, and professor of Persian in the University of London. The Triennial Gold Medal was founded in 1897 in commemoration of the sixtieth year of Queen Victoria's reign, and is awarded to an Oriental scholar in recognition of outstanding and distinguished services in the field of Oriental research, calculated to further the objects of the Society The last award was made to Sir Aurel Stein

THE senate of the Free City of Danzig has decided to found a State Academy of Practical Medicine consisting of eight professors and fifteen honorary lecturers, with Dr Kluck as director and Prof. Bürgeler as general secretary.

THE third International Congress of Comparative Pathology will be held at Athens on April 15-18, 1936, and will consist of three sections devoted respectively to human and veterinary medicine and the pathology of plant life Further information can be obtained from Dr. A. Codounis, 40 rue Didotou, Athens.

A CONFERENCE on "Population Studies in Relation to Social Planning" will be held under the auspices of the Population Association of America at the Hotel Willard, Washington, D.C., on May 2-4. The purpose of this conference is to focus attention on the importance of population studies in public affairs, especially in relation to planning Government activities, and to clarify problems on which further research is needed It will be primarily a conference between research workers in the field of population and persons engaged in administration or teaching in related fields. Further information can be obtained from the Secretary, 308 Victor Building, Washington, D C

WE are informed by M Ch Marie, general secretary of the International Committee of Annual Tables of Constants, 9 rue de Bagneux, Paris, 6, that the Academy of Sciences of the U.S.S R. has guaranteed for the next five years a contribution to the international fund for the publication of the Annual Tables In exchange, the U.S S R. Academy of Sciences is to receive a certain number of volumes issued by the Committee of the Annual Tables These volumes will be distributed among the universities and scientific institutions of the Soviet Union. Similar agreements have been already signed with the French Government, the Swiss Government and the Polish Academy of Sciences

WE regret to learn that the name of Prof. Ig Tamm was given incorrectly as "G Tamm" at the foot of the letter by Mr J. D. Bernal and Prof Tamm entitled "Zero Point Energy and Physical Properties of H_2O and D_2O" in NATURE of February 9 (p 229)

THE January number of *Watson's Microscope Record*, published by W. Watson and Sons Ltd , 313 High Holborn, W C 1, contains some interesting articles, among them an account of the manufacture of optical glass by Dr. W N Wheat, a note on projection with the microscope by W C. Clothier, and the first part of a description of the theory of the resolution of microscopic objects by E. M. Nelson These articles will be found of interest by many readers of NATURE, to whom the publication will be sent free on request by Messrs. Watson.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—A lecturer in mathematics at the City of Leeds Training College —The Director of Education, Education Department, Calverley Street, Leeds (April 10). A physical assistant in the Scientific Department of the Courtauld Institute of Art, 20 Portman Square, W.1—The Registrar (April 12) A City engineer and surveyor for the City of Nottingham—The Town Clerk, Guildhall, Nottingham (April 15). An assistant in psychology at Bedford College, Regent's Park, N.W.1 —The Secretary (April 27) A director of the Imperial Forestry Institute, Oxford—The Registrar, University of Oxford.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 511

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Production of Radioactivity by Neutrons

IN a previous letter[1] we described the measurement of the half-lives of a few elements made weakly radioactive by neutron bombardment The same neutron source and method have been used to investigate the radioactivity produced by slow neutrons in metallic zinc, cæsium nitrate, thallium acetate and bismuth carbonate, with the following results

	Half-life
Zinc	100 minutes
Cæsium nitrate	75 minutes
Thallium acetate	97 minutes
Bismuth carbonate	No detectable activity

In addition we obtained the 6-minute half-life for zinc, reported by Fermi and co-workers

The method we have used to calculate these half-lives, and also those published earlier, affords considerable accuracy in the case of relatively long lived elements, even when the activity, measured by counts per minute, is very weak Instead of plotting the rate of counting, dN/dT, as a function of time as is usually done ('differential method'), we have constructed an 'integral' curve (Fig. 1) in the following manner

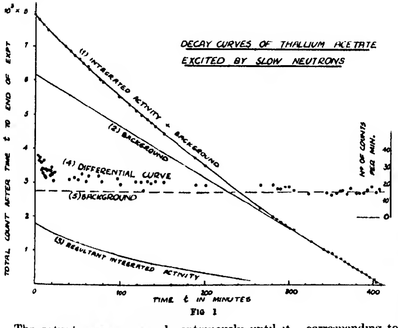

FIG 1

The activity was measured continuously until it had decayed to the normal background of the counter. A curve was then plotted to show the total number of impulses recorded, going backwards in time from the end of the experiment (curve 1). Part of this curve was due to the background, which contributed a total count increasing uniformly in time (curve 2). The difference between these two curves gave the true decay of the active substance (curve 3), it actually represented the number of excited atoms present at any time The points of a logarithmic plot lay very close to a straight line

The superiority of the integral curve method over the differential curve method is apparent from curves 3 and 4 The fluctuations in the counting rate make it exceedingly difficult to draw a smooth differential curve when the activity is weak

X-Ray Diffraction Patterns of Ice

DURING the last visit of the late Dr. E W Washburn to Toronto in the latter part of 1933, in an address on the properties of heavy water, he announced that water vapour, when condensed at very low temperatures, formed an amorphous rather than a crystalline solid He reported that he did not know of any X-ray evidence to this effect Mr. Fraser Oliver undertook to test this theory by taking X-ray photographs of the ice formed by condensation of water vapour on the outside of a copper rod The copper rod could be maintained at any given temperature The X-ray photographs were taken by the Hull-Debye-Scherrer method

In the accompanying figure [see over] are reproductions of two photographs showing the X-ray diffraction patterns of ice formed at − 85° C (*a*) and − 155° C (*c*) respectively, together with microphotometer tracings (*b* and *d*) of the films In the former case the diffraction pattern consists of lines characteristic of the close-packed hexagonal structure of ice, while in the latter there is one diffuse line corresponding to a spacing of 3·7 A, indicating the amorphous character of the condensate The lines due to diffraction by copper are indicated in both photographs, the other lines being those due to ice.

The results of our experiments, to be published later more fully, indicate that there is a critical temperature about − 110° C below which the

condensate is vitreous and above which crystals are formed. Barnes has already established[1] that ice formed by the freezing of water at 0° C exhibits

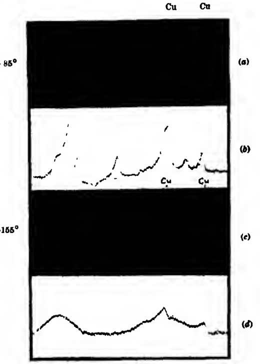

FIG. 1 X-ray diffraction patterns of ice from water vapour condensed at (a) -85° C, (c) -155° C, with corresponding microphotometer curves, (b) and (d)

the close-packed hexagonal structure and that no change takes place in the structure of ice between 0° C. and − 183° C.

Formation of Galactose in Vital Processes

SOME years ago, Prof Robinson[1] put forward in these columns the ingenious suggestion that the conversion of glucose into galactose in the organism is a direct one and due to an inversion of the configuration of the groups attached to the fourth carbon atom of the glucose molecule, consequent upon esterification of the hydroxyl group concerned by phosphoric acid. It is, however, now recognised that the terminal carbon atoms, as distinct from the fourth carbon atom, are those which are esterified in the fructose di-phosphoric acid involved in biological processes, and that in these latter the acid suffers disruption into the phosphoric esters of *d*-glyceric aldehyde and dihydroxy acetone

In these circumstances it is pertinent to recall first, the demonstration by Schmitz[2] that the α- and β-acroses resulting from Emil Fischer's classical synthesis of hexoses from *dl*-glyceric aldehyde (and dihydroxy acetone) are respectively *dl* fructose and *dl*-sorbose, and secondly, the interconvertibility, shown by De Bruyn and van Ekenstein[3], of *l*-sorbose (which, together with fructose, would result from combination of *d*-glyceric aldehyde with dihydroxy acetone) and *d*-galactose under the influence of alkali.

It may, therefore, be said that in principle a transition from *d*-glucose to *d*-galactose has been experimentally realised, and it may reasonably be asked whether Nature does not avail herself of these reactions for the conversion in question as well as for its direct synthesis in plants of one or both of these carbohydrates Failure to detect trioses in plant products is no more conclusive against this hypothesis than was the difficulty in detecting formaldehyde. Again, whilst it is true that *l*-sorbose has not been found in Nature, *d*-tagatose (which stands in the same relationship to *d*-galactose as fructose does to glucose) also has not been observed, and, on the other hand, *d*-sorbose, but not *l*-galactose, does occur naturally A more serious objection to a biological inter-relationship between *l*-sorbose and *d*-galactose perhaps lies in the fact that the former does not seem hitherto to have been fermented

Molecular Weights of the Phthalocyanines

THE accuracy attainable in determining the molecular weights of organic compounds from the density and cell dimensions of the crystal has recently been the subject of a note in these columns[1]. It is well known, of course, that the crystal data can in general give only a maximum figure for the molecular weight Thus in the relation

$$\text{Molecular weight} = \frac{\text{volume of cell} \times \text{density}}{\text{number of molecules per cell}},$$

a knowledge of the space group enables us to state the maximum degree of symmetry that the individual molecule may contribute to the structure, hence determining the minimum number of molecules in the unit cell and consequently the maximum molecular weight The true molecular weight will usually be a sub-multiple of this figure.

The metallic phthalocyanines[2] appear to offer an almost unique example of a class of compound in which an unequivocal determination of the *true* molecular weight can be made from the crystal data combined with an elementary analysis of the percentage of metal in the compound The results have proved of considerable importance in deciding the structure of these compounds, because their low solubility renders the ordinary methods of molecular weight determination difficult or impossible to apply, except in the case of the magnesium compound[3].

The compounds listed below all belong to the monoclinic system, and the space group C_{2h}^5 ($P2_1/a$) is clearly established by the examination of many hundreds of reflections. The maximum symmetry which the molecule can contribute is thus a centre, and if we assume that they display this symmetry, then the number of molecules per unit cell is two, and we obtain the following figures for the *maximum* molecular weight

	Nickel phthalocyanine	Copper phthalocyanine	Platinum phthalocyanine
a	19·9 A	19·6 A.	23·9 A
b	4 71	4 79	3 81
c	14·9	14·6	16·9
β	121·9°	120·6°	129·6°
Mol. per cell	2	2	2
Volume of cell	1186 A.^{3}	1180 A.^{3}	1186 A.^{3}
Density	1 63	1 63	1·98
Max mol. weight	586	583	712

Now the percentage of metal in the compound by elementary analysis gives the minimum possible molecular weight, namely, that of the molecule containing only one atom of the metal. The results are as follows:

	Nickel phthalocyanine	Copper phthalocyanine	Platinum phthalocyanine
Percentage metal	10·5	11·1	27·1
Minimum mol weight	559	573	720

As the values of the maximum and minimum molecular weights coincide (within the experimental limits), it follows that these figures represent the true molecular weight, and that the formula in each case is $C_{32}H_{16}N_8M$, where M represents the metal atom, which must reside at the centre of symmetry. The calculated molecular weights from these formulæ are 571, 576 and 707, for the nickel, copper and platinum compounds respectively. An interesting point is the practical constancy of the molecular volumes. The cell dimensions show that the large flat molecules must be well spread out in the *ac* plane. A full discussion of the many remarkable features of these structures, however, cannot be given here.

Nickel and platinum phthalocyanines were prepared by the general methods already described[3]. Details will be reported elsewhere. All three metallic compounds were obtained in a macro-crystalline form suitable for X-ray examination by vacuum sublimation at temperatures above 500° C. The crystal densities were determined by ordinary flotation methods. The improved technique described by Bernal and Crowfoot[1] would doubtless increase the accuracy very considerably.

It is possible that these methods might prove of value in the study of other complex compounds which contain a single atom of some element, provided that the necessary symmetry is displayed by the molecule.

Absorption Spectra of Substances containing Alkyl Radicals

IN continuation of previous work[1], the ultra-violet (2000–5000 A.) absorption spectra of the vapours of a series of compounds containing alkyl radicals have been measured, using absorbing columns of 5–100 cm and pressures 0·1–15 mm, except with the more volatile compounds, when pressures up to one atmosphere were employed. Extensive precautions have been taken to purify the substances studied, previous work having shown that minute traces of impurity may considerably affect the results obtained.

The absorption spectrum of mercury ethyl, $Hg(C_2H_5)_2$, with pressures greater than a few mm is completely continuous at wave-lengths greater than 2380 A. With higher pressures than hitherto used, the long wave limit may lie at greater wave-lengths. With lower pressures a system of diffuse bands is observed, prominent in which are the relatively intense pairs at 2362, 2345; 2305, 2290; 2250, 2235 A. Between these pairs are similar but less intense bands at 2327 and 2272 A. A much feebler band occurs at 2390 A. and another extremely faint and more doubtful one at 2560 A. The bands appear to degrade to the red and in general are broad. The system as a whole has an appearance in general similar to that observed with zinc diethyl, but there are differences. With longer columns there is a much feebler continuous absorption extending from 2420 to 2760 A. with a maximum at 2560 A., the position of the very faint band. This continuum appears to be independent of the former. The intervals and intensity relationships suggest that a ground state frequency involved is 498 cm^{-1}, modified in the excited state to 305, 294, 279. These frequencies are probably to be associated with valency vibrations of the metal-carbon link, which is excited electronically. The other prominent excited state frequency has values 1046, 1060, 1020, and 1075 cm^{-1}, and is probably related to a deformation oscillation in the C–H linkage (1090 cm^{-1}) as found in the case of diethyl zinc and many other examples[2]. If the feeble band at 2560 A. is genuine, there would also be a ground state frequency of 3276, which might be connected with a valency vibration in the alkyl group.

The above results agree with the previous conclusion with zinc dialkyls that the region of discrete bands is displaced towards longer waves in passing from methyl to ethyl compounds, for Terenin[3] has recently reported a system of bands with mercury dimethyl in the region of 2000 A., with a similar overlapping continuum extending to much higher wave-lengths at the higher pressures.

With germanium tetramethyl, absorption is continuous from *c.* 2330 A., as found for lead tetramethyl[4]. The continuous absorption previously reported for lead tetraethyl occurs at wave-lengths less than *c.* 2350 A. The bands at longer wave-lengths then given for the latter substance have been traced to the presence of a minute amount of benzene, which could not be entirely removed by the vacuum distillation.

With triethylamine at pressures up to 20 mm absorption was continuous from *c.* 2650 A., but the absorption limit may be at somewhat longer wave-lengths with higher pressures; with triethylphosphine the continuous absorption begins at *c.* 2500 A. and there are indications that in both cases at lower pressures with longer columns the continuum may be resolved into extremely narrow diffuse bands. With trimethylamine continuous absorption begins at *c.* 2600 A.

With dimethyl and diethyl ether there is a very feeble continuum at wave-lengths less than *c.* 2350 A., agreeing with the results of Scheibe and Grüneisen[5]. With diethyl sulphide, on the other hand, a well-marked continuum extends from *c.* 2300 A., or with higher pressures from slightly longer wave-lengths. At lower pressures a broad diffuse band appears at *c.* 2290 A. Using long columns and very low pressures, when the band at 2290 A. is scarcely visible, there is a faint continuous absorption from a noticeably sharp limit at *c.* 2240 A., and there are indications that the interval 2200–2240 (974 cm^{-1}) is important. It is of significance that a strong Raman frequency of diethyl sulphide is given as 977 cm^{-1}. Taken in conjunction with the results obtained for hydrogen sulphide, and ethyl mercaptan C_2H_5SH, it appears

that with the diethyl-sulphide the electronic excitation is in the S–C link.

Details of the above work and a discussion of it will shortly be published elsewhere, when the data for other compounds will also be given.

Radioactivity of Rubidium

KLEMPERER[1] has recently shown that $_{19}K^{40}$ is very probably the source of the natural β-radioactivity of potassium. This supports the suggestion put forward by the authors[2] based on Fermi's failure to observe induced β-radioactivity when calcium is bombarded with neutrons. Klemperer also suggested that $_{37}Rb^{86}$ is similarly the source of the natural β-radioactivity of rubidium. The effects observed when rubidium, yttrium and strontium are bombarded with neutrons support this suggestion as follows.

Hevesy and Høffer Jensen[3] have shown that $_{19}K^{42}$ formed from scandium has the same period as the radioactive isotope produced when potassium is bombarded with neutrons and it is, therefore, apparent that $_{19}K^{42}$ is formed by $_{19}K^{41}$ capturing a neutron. In a similar manner, the short-lived and weak β-radioactivity induced in rubidium when it is bombarded with neutrons is probably due to $_{37}Rb^{88}$ formed by $_{37}Rb^{87}$ capturing a neutron. If $_{37}Rb^{86}$ is also formed by $_{37}Rb^{85}$ capturing a neutron, then if this nucleus is the source of the natural β-radioactivity of rubidium, so few new nuclei are produced, that the long period will effectively prevent the observation of the corresponding disintegration electrons. It is noteworthy, as Hevesy[3] points out, that the disintegration electrons from the $_{19}K^{40}$ nuclei newly formed when $_{19}K^{39}$ captures a neutron cannot be observed experimentally for the same reason. It is also significant that Fermi and his co-workers[4] have observed no induced β-radioactivity when yttrium and strontium were bombarded with neutrons. Moreover, Szilard and Chalmers[5] have shown that heavy particles are probably ejected from indium ($Z = 49$) and v. Grosse and Agruss[6] have suggested that protons are probably ejected from uranium bombarded by neutrons. It seems, therefore, that under the conditions existing in Fermi's experiments, the emission of heavy particles may have followed neutron capture, and that this phenomenon prevails more generally than is to be expected. As, moreover, Chadwick and Feather[7] have shown that the five examples of neutron capture followed by α-particle emission are elements of odd atomic number, it appears that yttrium $_{39}Y^{89}$ is disintegrated under neutron bombardment thus

$$_{39}Y^{89} + n \rightarrow {}_{37}Rb^{86} + \alpha \uparrow .$$

Hence the failure to observe induced β-radioactivity with yttrium may be evidence in favour of Klemperer's suggestion, since the β-rays due to the newly formed $_{37}Rb^{86}$ would be too few to be observed experimentally.

In addition, of eight elements of even atomic number, six emit protons following neutron capture. Accordingly when strontium is bombarded with neutrons the action :—

$$_{38}Sr^{86} + n \rightarrow {}_{37}Rb^{86} + p \uparrow$$

may occur and, therefore, the failure to observe disintegration electrons from strontium bombarded with neutrons may be additional evidence in favour of Klemperer's hypothesis.

A New Band System of NH

A NEW band has been observed in the spectrum of a hollow cathode discharge through streaming ammonia. The band is degraded to the red and is of simple structure, consisting of single P, Q and R branches. Heads are formed at λ4502 and λ4523 by the R and Q branches respectively.

Preliminary analysis has shown that the upper level of the band is identical with that of the λ3240 band[1] of the $^1\Pi \rightarrow {}^1\Delta$ system of NH. The simple structure of the band shows that the transition involved is of the type $^1\Pi \rightarrow {}^1\Sigma$, so that the final level may be identified with the lower $^1\Sigma^+$ level predicted by Mulliken[2] for NH, but previously unobserved. Full details will be published shortly.

Action of Alternating Magnetic Fields upon Ferromagnetic Particles

WILL you allow me to demur to the statement on p. 349 of the issue of NATURE of March 2 that "No satisfactory interpretation of the phenomena was given" of certain experiments of mine on magnetism. The Physical Society invited me in 1928 to give an address on the subject of a 'discourse' which, at the request of the late Sir James Dewar, I had given in 1923 at the Royal Institution. My address at the Physical Society, published in abstract in the *Proceedings* of that Society (vol. 40, part 5, August 15, 1928) ended as follows:

"In his Royal Institution paper the Lecturer gave his reasons for attributing the repulsion to hysteresis. He sees no reason for changing that view. In that Paper fuller explanations of some of the effects for which there is not space here are attempted."

Readers of NATURE will, I think, find that the attribution of the effects to hysteristic repulsion was not made by me without very careful consideration.

In his book "The Interaction of Pure Scientific Research and Electrical Engineering Practice" (1927), Sir Ambrose Fleming describes the phenomena and on p 72 remarks

"In the Lecture above mentioned Mr Mordey discussed the various causes to which the above effects may be due, and he came to the conclusion, with which the author of this book agrees, that the effective source of the repulsion is magnetic hysteresis "

The Athenaeum,
London.
March 4

W M MORDEY

THE necessary brevity of the Research Items paragraphs makes it impossible to introduce the reservations and qualifications which would be appropriate in fuller accounts In the item referred to, the purpose was to direct attention to the main points in a paper by H S Hatfield Reference was made to the earlier work of W M Mordey, but full justice could not be done to it To Mr Mordey is due full credit for the discovery of the effects in question, and for his admirable investigations of them His work demonstrated very clearly a dependence on hysteresis This, however, does not enable an immediate explanation of the effects to be given In the last part of his Royal Institution lecture, Mr. Mordey appears to admit that he cannot find a satisfactory explanation of the phenomena, and there seems to be no suggestion of an interpretation on the lines proposed by Hatfield Until Hatfield put forward his convincing and essentially simple explanation of the observed movements of the particles, it seems fair to say that a full explanation of the phenomena had not been given

THE WRITER OF THE NOTE.

Definition and Measurement of General Intelligence

THE fundamental reason why general intelligence cannot be measured exactly by a hierarchical set of tests even if we agree that they define it (unless one of them tests nothing but general intelligence) is that in such a set there is always one more Spearman 'factor' than the number of tests: for each test has its own specific factor, and in addition there is the general factor.

Let z represent a set of k hierarchical test scores, each test standardised to unity, that is, let $z = Ls$, or

$$\begin{bmatrix} z_1 \\ z_2 \\ z_3 \\ \cdot \end{bmatrix} = \begin{bmatrix} l_1 & m_1 & \cdot & \cdot & \cdot \\ l_2 & & m_2 & \cdot & \cdot \\ l_3 & & \cdot & m_3 & \cdot \\ \cdot & \cdot & \cdot & \cdot & \end{bmatrix} \begin{bmatrix} s_0 \\ s_1 \\ s_2 \\ s_3 \\ \cdot \end{bmatrix} \quad (l_i^2 + m_i^2 = 1)$$

where s_0 occurs in every test, the other s's in one each Further, let q be the column vector $\{q_0\ q_1\ q_2\ q_3\ .\ .\ .\}$ where $q_0 = -1$ and $q_i = l_i/m_i$ ($i = 1, 2, 3\ .\ .\ k$) After q_k the q's are entirely at our disposal. q' is the transposed of q, and I the unit matrix. Then the orthogonal matrix

$$B = I - 2qq'/q'q$$

has the property that $L\bar{B} = L$, where $\bar{B}$ is the first $k+1$ rows of B. We can therefore write $s = \bar{B}t$ where it is clear that the 'factors' t are different from the 'factors' s although every test is still 'two-factor' and the correlations are unchanged Thus even if we agree that these tests define general intelligence, we do not know whether it is s_0, or t_0, or u_0, or v_0, or any of the infinite possibilities, all giving different measures for the general intelligence of the whole population. We can rid it of this indeterminateness by adding one or more 'singly-conforming' tests (a better term I think than 'non-conforming' which I used in NATURE of January 12, p 71)

Whether what the tests thus define is general intelligence is a question for the psychologist, not the mathematician

GODFREY H THOMSON.

Biology of Growth and Breeding

THE observations by Cottam[1] on reproduction and growth of the sea-grass, *Zostera marina*, are of considerable biological interest He suggests that perhaps the *length* of the growing season may be an important factor in determining the breadth of the leaves in any habitat, and points out that Setchell has shown that reproduction in the species occurs between 15° and 20° C and growth in the range 10°–20° C. In recent work on increase in shell-area in the oyster[2], I found that there is large spring as well as autumn growth in the Fal Estuary, but only a trace of growth in spring, with a large summer or autumn growth in the River Blackwater Now in the Fal Estuary the temperature rises slowly from about 10° in winter, whereas in the more insular Blackwater oyster beds the rise is very rapid. Breeding begins in the oyster[3] at about 15°–16° C, and increase in shell-area ceases at the onset of the breeding season There is thus a longer spring growing period in such hydrographical situations as the Fal Estuary than in localities like the Blackwater.

The parallel of growth and breeding in the oyster with *Zostera marina* is striking, as also is the convergence in their biology It is well known that many animals breed at a relatively small size under relatively high temperatures[3], and the explanation offered[3] is that there are, in many non-stenothermic animals, growth and breeding metabolisms governed by different temperature ranges, which give rise to a physiological antagonism between breeding and growth It may therefore be deduced that when such an organism has attained a *certain level of maturity*, it will begin to breed providing temperature and other conditions are suitable This level of maturity may occur at a small size, and if breeding conditions do not then obtain, growth may continue and produce a larger or different facies of organism before breeding occurs. There are winter as well as summer breeders, and the habitat and rhythms of the whole life cycle need to be studied in each species for a full understanding of the biology The observations made in the study of the habitat of the oyster and the cockle[4], it is interesting to note, may be of value in leading to an understanding of the broad-leaved *Zostera* found in deeper water off the coast of Great Britain.

Experimental Induction of Coupling in *Xenopus laevis*, with the Production of Fertilised Eggs

In the course of an investigation into the sexual cycle of *Xenopus laevis*, the South African clawed toad (Shapiro and Zwarenstein[1], Shapiro and Shapiro[2]), certain outstanding differences in the sexual behaviour of this amphibian were observed under laboratory conditions as compared with natural conditions prevailing in the pond. It was noticed, among other things, that mating activity was never in any circumstances exhibited in captivity in the laboratory even at the height of the breeding season (July to September in South Africa).

In order to investigate the factors concerned with the mating reflex, toads fresh from the pond were brought into the laboratory at monthly intervals from August 1934. These toads were divided into three groups with appropriate controls. (Details of these experiments will be given in a forthcoming publication.)

In the first group, both the male and the female toads were injected with an acid extract of sheep's anterior pituitary, with an extract of pregnancy urine (prepared according to the method of Katzman and Doisy[3]) and a similarly prepared extract of male urine. In the second group, females only and not males were injected with these extracts. In the third group, males only and not females were injected similarly.

The results were as follows:—

A maximum percentage of coupling took place when both males and females were injected with either pregnancy urine or anterior pituitary extract.

A smaller percentage of coupling occurred when females only and not males were injected. This percentage rapidly dwindled to zero, the further from the breeding season in point of time the injections were made.

No coupling was observed when males only and not females were injected, even at the height of the breeding season.

In no case did the male urine extract induce the act of coupling or ovulation.

Colour change in *Xenopus* (which involves a pituitary mechanism, Hogben and Slome[4]) did not affect the mating reflex.

Several pairs of coupling toads were killed at the beginning of the act of mating and their oviducts were found to be entirely free of ova. Ovulation has also been observed without concomitant coupling.

In all, the mating reflex has been induced experimentally in 71 different pairs of toads with pregnancy urine extract and in 20 different pairs with anterior pituitary extract. The act of coupling lasts 24–48 hours, and fertilised ova were recovered from the containers of such coupling pairs. The ova were successfully reared for 4 5 months to the tadpole stage.

By injection of the above extracts coupling can be induced in the laboratory not only near the breeding season, but also in midsummer, that is, the mid-point between two breeding seasons. In all cases tadpoles have so far been reared successfully from such fertilised eggs.

The experiments also suggest:

(1) That a female stimulus initiates the response by activating the male.

(2) That the anterior pituitary is involved in this complex pattern of motor behaviour.

(3) That the pituitary mechanism associated with colour change in *Xenopus laevis* is not concerned with the mating reflex.

(4) That if the same chemical substance initiates ovulation as well as coupling, it initiates these two activities at different thresholds.

A further investigation into the details of the mating reflex is being carried out.

Use of Cellulose Films in Palæontology

REFERENCE has been made by S. Leclerq[1] and J. E. Appel[2] to the use of cellulose films or 'peels' in palæontology, but there does not seem to be any published account of the procedure involved. In the method outlined below, which was suggested to me by Prof. L. J. Wills, and used in the first place to record the internal structure of rugose corals, a cellulose cast is made from an etched surface, and structural detail stands out solely by reason of the optical effect of textural variation.

The cellulose solution is most easily prepared by diluting the commercial preparation 'Durofix' with about twice its volume of butyl acetate; I have also found very satisfactory the solution advocated by R. Graham[3].

The cut surface of the coral is ground with fine carborundum, etched for five to ten seconds with dilute (10 per cent) hydrochloric acid, washed and allowed to dry; the finer the organic structure, the shorter is the time of etching required. The specimen is mounted on plasticine so that the etched surface is horizontal, and after moistening the latter with butyl acetate as a precaution against air bubbles, the cellulose solution is poured on to form a layer about 2 mm. thick. The solution dries in 3–5 hours, and the edge of the film is then lifted from the specimen with a sharp blade, and the whole film peeled off. The film can conveniently be preserved between glass plates bound together at the edges.

The method is applicable to any fossil in which a difference in relief and texture between the organic parts and the surrounding matrix can be obtained by etching with hydrochloric or hydrofluoric acid. In the preparation of serial records it is advisable to embed the specimen in plaster of Paris before grinding; the distance between successive peels can be measured with a spherometer. Peels from corals and brachiopods show not only the outlines of the skeletal elements, but also the detailed fibrous or lamellar structure of these; some which were prepared in 1931 are still free from contraction or discoloration.

An important possibility is the distribution of duplicate records of type specimens, since a great many peels can be made from a prepared surface without re-grinding or re-etching.

A Remarkable Whirlwind

'DUST DEVILS', or rotating columns of sand travelling rapidly across open spaces, are not uncommon objects to desert travellers Their height and breadth is often very considerable and the violence of the eddies causing them very great

The smallest of this type I have seen was only about 5 ft high, that is, the visible column of sand, and less than a foot in diameter It passed so close to me that it was easy to see its narrow cycloidal path marked on the sand, which was deposited and lifted as the eddy travelled on at not less than 15 miles an hour, although the wind was actually very light

I recently encountered a much more remarkable example while walking over a smooth surface of desert on a flat calm day Hearing a swishing sound behind me, I turned and observed a large revolving ring of sand less than a foot high approaching me slowly It stopped a few feet away and the ring, containing sand and small pieces of vegetable debris in a sheet less than one inch thick, revolved rapidly round a circle of about 12 ft diameter while the axis remained stationary It then moved slowly round me after remaining in one spot for at least thirty seconds, and slowly died down It would be interesting to know if others acquainted with the desert have come across similar examples of a broad, flat eddy

The ancient superstition among desert tribes that these whirlwinds are spirits, called 'afrit' or 'ginni' (the 'genii' of the "Arabian Nights"), would seem to have a reasonable foundation in face of such an 'inquisitive' apparition

Cairo J. L. CAPES

Thermal Decomposition of Acetaldehyde

IN a letter in NATURE of January 12, Mr Hinshelwood stated that further work in his laboratory by Dr Winckler on the thermal decomposition of acetaldehyde had refuted the criticism of his work contained in a communication to the Royal Society of May 10, and in letters in NATURE of October 13 and 27, 1934 The results of this work appear in a paper which he communicated to the Royal Society at a meeting held on March 7, at which it was read in title only The results are held to yield no evidence that the reaction represented by the equation, $CH_3CHO = CO + CH_4$, is appreciably heterogeneous, or that it depends upon a chain mechanism

Mr R V Seddon and I have also been engaged in a research on the same subject, with results which appear to us to point in exactly the opposite direction The work is not completed, and the results may not be published for some time, so we ask permission to point out that the last word has not been said upon this subject

M W TRAVERS

Points from Foregoing Letters

THE half-life period of radioelements formed when metallic zinc, cæsium nitrate, thallium acetate and bismuth carbonate are submitted to bombardment by slow neutrons is given by Prof J C McLennan, Mr. L G Grimmett and Mr J Read. The authors also describe a way of plotting the observed activity, which allows of a more exact determination of the life period of relatively long lived radioelements.

Prof E. F. Burton and Mr. W F Oliver submit photographs of X-ray diffraction patterns indicating that at very low temperatures (below −110° C) water vapour solidifies in amorphous form, while above that temperature it forms crystalline ice.

Galactose, a constituent of the milk sugar molecule, is apparently formed in the animal body from glucose, which has the same chemical composition, but different structure Prof Robinson has suggested that the change from glucose to galactose occurs through a relatively simple rearrangement of the atoms (brought about by phosphoric acid) Prof J Kenner now suggests that the glucose molecule is first broken up and then recombined to form galactose

Molecular weights were first determined from combining ratios, osmotic and gas pressure, etc Recent physical methods (for example, ultracentrifuging) sometimes give results differing from those obtained by the original methods A way of obtaining the maximum molecular weight from density and X-ray crystallographic data is described by Dr J. Monteath Robertson, Dr. R P Linstead and Mr. C E. Dent. They show that, in the case of metallic compounds of phthalocyanines, it gives values agreeing with those obtained by the combining ratio method.

Prof. F. H. Newman and H J Walke adduce reasons supporting Klemperer's view that the natural radioactivity (emission of electrons) of rubidium is due to the presence of an isotope of mass 86

From the fact that independent intelligence test scores fit 'tetrad' formulæ which equate to zero, Spearman has deduced that a general intelligence factor g must exist in addition to special abilities Prof G. H Thomson explains that though such hierarchical tetrad sets may prove the existence of g, they cannot in general measure it unless one of the tests measures general intelligence alone, or unless a 'singly-conforming' test is added

In the case of animals which can live under various temperature conditions (non stenothermic) there may be temperatures which are favourable for growth and not for breeding Prof J H Orton finds that the oysters in the Fal Estuary show a larger spring growth than those in the River Blackwater, he ascribes this to the fact that the temperature in the Fal Estuary remains longer in the spring between 10° and 15° C (which promotes growth), while that of the River Blackwater rises more quickly to 15° to 20° C (which facilitates reproduction)

Dr H A Shapiro has investigated the effect of extracts of the anterior pituitary, of pregnancy urine, and of male urine, upon the mating instinct of the South African clawed toad. He finds that coupling is induced by the first two extracts He deduces, among other things, that the anterior pituitary is involved in the mating reflex and that a female stimulus initiates the response in the male

Mr A J. Butler describes the technique of preparing cellulose film casts from the etched surface of corals and other fossils Such casts show structural details and have the advantage that a number of identical reproductions can be readily obtained to serve as type specimens.

Research Items

An Orissa Cult Research in India during the last half century has brought to light the unexpected existence of a number of obscure cults, such as the masked Buddhism of Bengal, fire-worship in a remote corner of Rajputana, and curious agricultural cults in Bihar. Such survivals are compared by Sarat Chandra Mitra in a recent communication (*J. and Proc. Asiat. Soc. Bengal*, New Series, **30**, No. 1) to a cult of a horse-headed goddess, of which evidence has been discovered in Orissa. Prof. Priya Ranjan Sen has found the "mare-headed Bāsulī" worshipped in various localities in Orissa by Keots and allied castes. The cult has a sacred book, said to have been written in Uriya by Achyutā Dās, one of the five companions of the great Vaishnava reformer Chaitanya Deva. He thinks that Bāsulī was originally a Dravidian deity, who was gradually transferred to the Hindu Pantheon. Her deityship is represented by an image with a horse's head and sometimes by a horse wholly made of wood. From a recently discovered folk-ballad, the development of the cult can be traced to a horse which was born from the water to help, and then serve as the mount of, a Dāsa king. It is hence inferred that the horse is the totem of the Keots and allied castes of Orissa, for the horse in the ballad is evidently a spiritual being connected in some way with the origin of the Keots—possibly their ancestor to whom they paid homage in the form of a wooden image, afterwards transformed into a goddess with a horse's head. The Khangars of Bundelkhand have a horse for their totem, but do not worship it. Reference is also made to the peacock totem cult of the Mori sept of the Bhils, and the tiger and hyæna totems of the Orāons, the Kurmi sept of the Mahilis of the Santal Parganas and the Jagganāthi Kumhārs of Orissa. If this contention can be maintained, it provokes dissent from the opinion of Risley that "the religious side [of the system of totemism] has fallen into disuse" in India.

Early Pottery in Beth Shan. In 1933 the expedition to Beth Shan of the University Museum, Pennsylvania, then in the tenth year of its work, carried its excavations down to virgin soil within a restricted area with the view of discovering the depth and nature of the levels which underlay the Middle Bronze Age stratum of about 1700 B.C. at a depth of thirteen metres (43 ft.) then being explored. A stratified succession of eight occupation levels was discovered, through a depth of 8.50 m. below the level previously reached, which goes back to an occupation of pit-dwellings in virgin soil earlier than anything previously found in Palestine. The pottery from these eight levels, which cover twelve separate periods of rebuilding, has been described and figured by Mr. G. M. Fitzgerald (*Museum J.* (Philadelphia), **24**, No. 1). For convenience of description the pottery is classified into a threefold division: Levels xviii-xvi, xv-xiii, and xii-xi, which represent conspicuous changes in the character of the pottery, but cannot be assumed to indicate any change or interruption in occupation until the end of the Early Bronze Age. There are no sterile layers or burnt strata between any of the levels. The ware of the pit-dwellings is poorly burnt and gritty, hand-made, and often showing signs of a red slip or wash. In levels xii-xi the dominating characteristic is an abundance of lustrous burnished pottery which is unlike anything in the levels below. This is the Kherbet Karan ware, so called from the site on the lower side of the Sea of Galilee where it was first found. It may be regarded on one view as here marking the first period of the Middle Bronze Age.

Dynamics of Animal Populations. Several mathematicians have recently been trying to codify into a harmonious system of formulæ the facts about increase and periodic fluctuations in animal populations. A. J. Lotka, a pioneer worker in this field before the War, has published the first part of a monograph on the subject ("Théorie analytiques des associations biologiques", Actualités scientifiques et industrielles, 187. Exposés de biométrie et de statistique biologique No. 4. Part 1. Principles. Pp. 45. Paris: Hermann et Cie, 1934). Changes in numbers in an animal community are really the redistribution of available matter and energy, through the selecting and concentrating powers of various living organisms, and as such can be studied by some of the mathematical equations employed for defining physico-chemical reactions. Equations expressing the interaction of two species are discussed, with special reference to the rates of increase, as a preliminary to the consideration of more complicated cases.

Historical Review of the Woodcock. The January number of the *Canadian Field Naturalist* is given over to a historical review by Henry Mousley of the knowledge of the habits and anatomy of the woodcock, compiled from the earliest drawings and accounts to those of the present day. Both the European and American species (*Scolopax rusticola* and *Philohela minor*) are included in the review, and the author has been fortunate in having at hand the 5,000 original drawings and paintings of birds and other animate things in the Blacher and Emma Shearer Wood Libraries of McGill University. For example, a drawing of about 1805 showed that the flexibility of the upper mandible of the woodcock's bill was known to the artist, although the discovery has been attributed to Turnbull so late as 1890, the only reference to the character, earlier than the drawing mentioned, is by Naumann in 1799. The story of the discovery of the unusual position of the ear and vertebral column relative to the skull as a whole is traced, as well as other points of interest.

Life-History of *Philine*. Mr. Herbert H. Brown has made a detailed study of the tectibranch *Philine aperta* (*Trans. Roy. Soc. Edinburgh*, **58**, Part 1, No. 9, 1934). This mollusc is common in the estuaries and creeks of the British coasts, burrowing in the sandy mud, especially above low-water mark, and is often associated with *Zostera*. In Loch Sween, where the author collected his material for the present research, it is one of the victims of the recent *Zostera* disease, its numbers being much reduced in places. Part 1 deals with the anatomy of *Philine*, Part 2 with its development. The eggs are laid in gelatinous strings by which the mass is firmly moored in the mud or sand. The newly hatched veliger has a simple shell and small bilobed velum. A conspicuous feature of the animal is a round black mass on the right side

in the body wall This is the so called 'secondary kidney', which does not itself give rise to the true kidney, the latter replacing it in due course The larva grows quickly and gradually metamorphoses into the adult After the velum is lost, the young animal may still be found in the plankton but soon finds its way to the bottom The paper is well illustrated with text figures of the anatomy of both adult and larva

Sandflies and Kala Azar. In their further investigations on Mediterranean kala azar, S Adler and O Theodor (*Proc Roy Soc Lond*, B, 801, Feb 1935) have found that infections of the proboscis are rare in sandflies infected with the Maltese and the Catania strains of *Leishmania infantum*, and that the majority of such infections of the proboscis occur towards the end of the sandfly season. They also found that only those sandflies (*Phlebotomus*) which have the flagellate stage of *Leishmania* in the distal part of the proboscis are capable of depositing the flagellates in the skin during the act of piercing The flagellates are passively deposited during the movements of the epipharynx in the tissue It is inferred that the majority of infections in human beings are acquired towards the end of the sandfly season, and this view is supported by the fact that half of all the cases in Catania are diagnosed from the end of April to the middle of May, that is, from six to eight months after the end of the sandfly season. They consider it is highly probable that there are distinct strains within all the recognised species of human *Leishmania* In the area in which the investigations have been carried out, dogs form reservoirs from which sandflies obtain *Leishmania*, the number of sandflies which infect themselves on human cases is comparatively small

Finger-and-Toe Disease of the Cabbage Family. Dr. G. Potts has recently published a paper giving a large amount of information about the incidence and control of finger-and-toe disease of cruciferous plants (*Trans. Brit Mycol Soc*, 19, No 2, Jan 1935) The experiments were performed before 1905, and it is rather a reflection on the slow progress of knowledge about this disease, that the paper is still of great interest and significance Severity of attack by the fungus varies with the host, and symptoms for a considerable number of plants are given. Many experiments were directed to a study of the effect of soil reaction on the virulence of the pathogen The application of sodium carbonate to the soil invariably controlled the disease more thoroughly than lime, though *Plasmodiophora* was found to occur and produce the characteristic swellings in highly calcareous soil, and in soil devoid of organic matter. Several questions as to infection by spores were also investigated, and the account has been brought up to date and correlated with more modern work on the same subject

Mycorrhiza in Relation to Forestry. There is general agreement that healthy growth of pine and other conifer seedlings is always accompanied by free development of fungus-roots, and that poor growth and lack of vigour are associated with defective mycorrhiza formation No satisfactory evidence has hitherto been offered that the two phenomena are causally related, but M. C Rayner (*Forestry*, 8, No. 2, 1934) now describes field experiments and laboratory cultures with various species of *Pinus* which prove that the presence of mycorrhizas normal for the species is causally related with proper nutrition and healthy growth of the seedlings In cases where mycorrhiza development was defective, the condition was relieved and growth of the seedlings stimulated by inoculating seed-beds with small amounts of humus containing active mycorrhizas of the species. But the beneficial effects following inoculation are controlled by factors operating within narrow limits, since they are readily influenced by variation in experimental treatment, as, for example, the date of sowing Hence it is important that a suitable technique for promoting mycorrhiza formation by means of humus treatments should be carefully worked out and standardised. Evidence was obtained of close correlation between particular soil conditions and the behaviour of specific mycorrhiza-formers, disturbances leading to replacement of mycorrhizas by parasitic pseudo-mycorrhizas with consequences adverse to the health and vigour of the hosts On the heath soils used in the field experiments, it was found that mycorrhiza deficiency was due to inhibiting soil conditions rather than absence of appropriate mycorrhiza-formers, and the inhibiting action was reversed by the addition of organic composts to the seed-beds, resulting in mycorrhiza development, accompanied by increases in root and shoot growth which could not be attributed to direct manurial action

Hydrology of Asia. Accompanying a paper on "Die Gewässer Eurasiens", Dr F Jaeger has produced in *Petermanns Mitteilungen* of January 1935 a novel map of the water features of Europe and Asia In addition to the topographical features in which water plays a part, there are differentiated the wet and the dry climates, the limits of frozen soil, the occurrence of ice dams on the rivers, the limits of snowfall and the occurrence of glaciers A further useful feature of the map is the distribution of the main types of surface apart from vegetation, such as sand, swamp, karst, etc The map is on too small a scale (1 30,000,000) to show any country in detail, but is useful in illustrating broad contrasts

Scottish River Gauging. We have received from River Flow Records, Parliament Mansions, S W.1, a further memorandum (No 2) on the subject of river flow measurement on the Aberdeenshire Dee, which was originally noticed in NATURE of September 8, 1934, p 352 The development of the records is shown by three documents, the first exhibiting a standard form for water level records intended to be completed at the Water Engineer's Office, Aberdeen; the second a stage-flow table compiled from river gaugings taken, mainly, between mid-September and mid-November 1934, with two types of apparatus—in all, about 7,000 velocity observations were made, including continuous night and day work during three high floods, the third document is a quarterly records diagram, exemplified by readings from the River Garry, at Invergarry, the diagram being designed to present the complete data of records relating to water levels, aggregate rainfall and run-off in a form suitable for publication It is anticipated that the record diagrams for the River Dee for the whole year 1934 will be completed in a few weeks time and that, thereafter, other water recorders will be established at Balmoral and Dinnett, with a view to the completion of the flow gauging, the records being kept at an office in Aberdeen.

The Claude Power Scheme. The December 1934 issue of the *Annals of the Brazilian Academy of Sciences* contains an address by Georges Claude, of the Paris Academy of Sciences, on the present state of his work on the use of the sea as a source of power His proposal is to evaporate surface water by reducing the pressure on it to about 1/100 atmosphere and condense it by means of water at a lower temperature brought up from a depth of 600–700 metres His attempt to carry out this project on the coast of Cuba failed owing to the destruction of the cold water tube 2 kilometres long by a storm His present attempt is being made at sea 70 miles south of the Bay of Rio de Janeiro on board the S S *Tunisie* The cold water tube is here vertical, and of sheet iron insulated by wood ; it is 650 metres long and 2·5 metres in diameter The surface water has an average temperature of 24 5° and the lower water 6 5° C The tube is supported by a float independent of the ship, a flexible tube connecting the two. The vapour produced by the evaporation of water taken from the surface passes through turbines to the condensers, and the power available is estimated at 1,300 kilowatts, but the figures on which this is based are not given, nor are the heats of evaporation and condensation mentioned.

Combustion and Explosion. The *Zeitschrift für Elektrochemie* of March 1935 contains a review by Dr W Jost of the "Mechanism of Explosions and Combustions" Chain mechanisms, which are now so much in the limelight, do not occupy much space in this review, although Semenoff's work is frequently referred to , but ample references are made to the experiments of Bone, Finch, Wheeler and Coward, in Great Britain, and of Bernard Lewis in America, as well as to Haber's experiments in Germany Two tables of observed and calculated velocities of detonation are cited from Lewis's work, and the literature references number exactly one hundred. The wide scope and unbiased character of the discussion make this review of real value as a summary of the present position of this important subject

Early Stages of the Electric Spark. U. Nakaya and F Yamasaki have studied the formation of ions in a spark gap by putting the gap in a Wilson cloud chamber (*Proc Roy Soc.*, A, Feb. 1) Immediately after the expansion, the potential was applied to the gap for a short time by means of an impulse generator, and a photograph was taken a few hundredths of a second later Distortion of the ion distribution by electric winds was avoided by the short time of application of the potential The potential was usually insufficient to produce a fully developed spark, but violet brushes could be seen in some of the experiments At low voltage a spindle-shaped ion cloud appears at a point on the negative electrode ; at a higher voltage a bundle of streamers appears in addition on the positive electrode These grow longer and take a branched form when the potential is further increased. These figures have a resemblance to the positive Lichtenberg figures obtained on a photographic plate

A Spectroscopic Determination of e/m. Work carried out before 1929 did not give good agreement between the values of e/m obtained for free electrons and those obtained spectroscopically. This discrepancy has tended to disappear in more recent work. C. D. Shane and F H Spedding (*Phys Rev.*, Jan. 1) have made a precise spectroscopic determination by measuring accurately the frequency difference between corresponding parts of the line structure of $H^1\alpha$ and the heavy hydrogen line $H^2\alpha$. The method gives directly the ratio of the mass of the electron to that of the hydrogen nucleus, and e/m may then be calculated when we know the Faraday electrolytic constant A liquid-air cooled discharge tube was used as light source, and a Fabry Perot étalon combined with a large grating was employed to resolve the lines The separation was found by analysis of microphotometer curves The final value is $e/m = 1\ 7579 \pm 0\ 0003 \times 10^7$, which agrees with other recent results by the two methods

Empirical Heat Capacity Equation. The classical form of equation relating heat capacity to temperature . $C_p = a + bT + cT^2 + dT^3 + \ldots$, is known to fail in certain cases, and it is proposed that it should be replaced by an equation of the type $C_p = a + bT + cT^n$ The success of this equation depends upon the value of n employed, and it is desirable that a single value of n should be selected which gives satisfactory values for a wide range of substances, and it is also essential that the equation shall be readily integrable for the purpose of arriving at values for the energy J Chipman and M G Fontana (*J Amer. Chem. Soc* , 57, 48 , 1935) propose the equation in which $n = -\frac{1}{2}$, and show that for several typical substances, including gases, magnesia, graphite and calcium silicate, the equation gives results which are sufficiently accurate for thermodynamic calculations, the temperatures in all cases extending to above 1,000° C The data for the solids used are experimental , those for the gases are theoretical values calculated from spectra An equation of the first—power series—type, proposed by Eastman, and one proposed by Kelly, were found to be not at all trustworthy when extrapolated beyond the range for which each was intended.

The Lead Accumulator. In three recent papers (*J. Amer. Chem Soc.*, 57, 9, 27, 33 , 1935), H. S. Harned and W J Hamer have reported experimental work and calculations which have an important bearing on the thermodynamic theory of the lead accumulator. They conclude that the reversible cell reaction is that proposed by Gladstone and Tribe .

$$PbO_2 + Pb + 2H_2SO_4 = 2PbSO_4 + 2H_2O$$

The experimental work involved the measurements of the electromotive forces of various types of cells at different acid concentrations and temperatures In the calculations, the activities of water in sulphuric acid solutions, the activity coefficients of sulphuric acid in aqueous solutions of concentrations 0–17·5 M and at temperatures from 0 to 60°, and also thermal data are involved The results are compared with measurements of vapour pressures, freezing points and heats of dilution, and very satisfactory agreement is found. A number of interpolation equations have been worked out and a very comprehensive study of the electrode potentials and reversible electromotive forces of cells related to the lead accumulator is presented in a condensed and convenient form. One of the matters investigated was the preparation of lead dioxide by different methods, the specimen prepared by electrolysis of a solution of lead nitrate and nitric acid giving the most consistent results.

Atmospheric Electricity in Australia

THE work initiated by the late Prof W. G Duffield on the foundation of the Solar Physics Observatory at Canberra included preparations for the study of atmospheric electricity. This work is now yielding results, a few months ago Mr. A. R. Hogg published an analysis of observations of conductivity and of the nucleus-content of the air, and now a memoir on potential gradient prepared by Mr C W. Allen has been printed in the series of official publications of the Commonwealth Observatory*.

Potential gradient has been recorded at various places with more or less precision for the best part of a century, but it is only within the last few years that clear ideas as to the significance of the measurements have been developed. Mr. Allen has been able to incorporate some of the new ideas in his discussion of the records obtained at the Commonwealth Observatory, and there are many points of interest in his memoir.

The Observatory is on Mount Stromlo, a flat-topped hill 780 m above sea-level, 200 m above the surrounding country, which is 12 km. west of Canberra and 120 km. from the sea-coast. The only sources of pollution in the atmosphere are the occasional bush fires It is not likely that these have affected seriously the results which Mr Allen sets out in his memoir, which deals in the main with the potential gradient in fine weather.

It is well known that the upper atmosphere is at a high positive potential compared with the ground For this purpose we may regard the upper atmosphere as being either the Heaviside layer or the atmosphere at a height of 10 km or so Under the influence of this high potential, a current, the air earth current, flows down to the ground The strength of this current varies inversely with the resistance of the air column. The potential at a height of say one metre above the ground is proportional to the current and to the resistance of the air in this lowest metre The potential gradient may also be regarded as a measure of the negative surface charge on the ground or of the complementary positive charge distributed through the atmosphere For the interpretation of observations of potential gradient all these factors must be borne in mind

Mr Allen has looked for the influence, at Canberra, of the world-wide changes in the potential of the upper atmosphere, by studying the changes of potential gradient on days with continuous strong wind, realising that on such days the changes of conductivity of the lower atmosphere will be comparatively small He finds that under these conditions the diurnal variation of potential gradient approximates to the type found over the oceans, a type in which the maximum gradient occurs at about 19 h G M T, the minimum at about 3 h G M T According to Wilson the potential of the upper atmosphere is maintained by thunderstorms and, as was first pointed out by Appleton, the diurnal variation is due to the fact that the activity of thunderstorms is at its maximum when it is afternoon in one of the tropical continental areas and at a minimum when it is afternoon over the Pacific When the distribution of thunderstorms is studied in detail, it is found that the regions of activity are farther west in the northern summer than in the northern winter, so that the maximum activity occurs later in the Greenwich day in the former season The corresponding delay in the occurrence of the maximum potential gradient is not manifest in the rather irregular graphs which represent Allen's Canberra results, but the corresponding shift in the phase angle of the 24-hour term comes out in harmonic analysis

The effect of wind on the potential gradient at Mount Stromlo is curious The gradient is comparatively small during calms and with very light winds but has its maximum value with winds of 5 m p h A falling off with stronger winds occurs with south-east winds but not with north-west winds (these are the two prevailing currents) Allen endeavours to explain the minimum in calms by the 'electrode effect', but this explanation should, as he would be the first to admit, be tested by observation The test would be straightforward, for the gradient as published is deduced from the potential difference between the ground and a collector at a height of 2 4 metres If the 'electrode effect' is there, a higher value of the gradient would be found by using a collector only one metre above the ground

Enough has been said to indicate the high value of Mr Allen's memoir It is to be hoped that his methods of analysing potential gradient records will be copied and extended elsewhere

One curious detail must not be forgotten It appears that in summer the sea breeze reaches Mount Stromlo in the early evening The arrival of the sea-breeze is always marked by a drop in the potential gradient, and frequently there is a negative gradient for a few minutes The more sudden and violent the wind change the more prominent is this effect The gradient soon becomes positive again and is generally higher than previously. Is this evidence that at the head of the sea-breeze little whirlwinds are generated, raising dust which settles and leaves the air negatively electrified, so that a negative space charge is carried onwards for a considerable distance? It seems likely F. J. W. W.

* Memoirs of the Commonwealth Solar Observatory, Mount Stromlo, Canberra, Australia. Memoir No 4: Atmospheric Potential Gradient Observations at the Commonwealth Observatory, Mount Stromlo, Canberra By C. W Allen Pp 47 (Canberra Government Printer, 1934.)

Man's Place among the Primates

PROF. W. E LE GROS CLARK, Dr. Lee's professor of anatomy in the University of Oxford, contributed a closely reasoned review of the present position of the questions of the evolution of man to the recent congress of Anthropological Sciences which is now published in full (*Man*, January). The main conclusions at which he arrives are summarised below.

The evidence suggests that one sub-order of the Primates, the Lemuroidæ, branched off at least at the very beginning of the Tertiary period from a basal primate stock which had been segregated from a generalised placental mammalian group in the Cretaceous period, and that any resemblance that it shows to the monkeys at later stages of its evolution is due to parallel development. Another sub-order,

the Tarsioidea, also a branch from the basal primate stock, approximates much more closely in its evolutionary tendencies to those of the higher primates It is not improbable that the latter arose from fossil tarsioids in Eocene times, originating from the earliest and most primitive members of the group Some of the resemblances shown by the tarsioids to the monkeys are due to parallel evolution

The evidence also suggests that the monkeys diverged from the main stem of evolution very soon after the tarsioid stage had been passed Of all the primates, the anthropomorphous apes stand nearest to man structurally, but there is no reason for believing that they derive from a common ancestor so distant and so generalised that it would not come into the category of the anthropomorphs It is necessary to postulate an anthropomorph ancestry for modern man, though this does not mean that in the line of human descent there ever was a form which showed the characteristic specialisation of modern anthropoid apes such as the great elongation of the arms and degeneration of the thumb

It is certain that the earlier anthropomorphs were relatively generalised creatures, in which the primitive proportions of the limbs were still retained, and yet they would have shown a grade of development of brain, skull, dentition, etc, which would have entitled them to be called 'anthropoid apes'. There is every reason for supposing that man was initially derived from such a type The evidence of foot structure, as shown by Dr Morton in America, is decisive Structural features afford evidence that the foot of modern man is derived from a foot once used for grasping purposes.

At what stage in the evolutionary differentiation of the anthropomorphs did the human stem become segregated from that which led to the modern anthropoid apes ? The mandible and lower dentition of the fossil *Parapithecus* of lower Oligocene age are regarded by most as representing a small and very generalised member of the Anthropomorpha, which may have formed the basis for the development of the later types This may involve regarding the platyrrhine and catarrhine monkeys as precocious and specialised offshoots of the anthropomorphous stock.

Of the same geological age as *Parapithecus* is *Propliopithecus*, which so closely resembles the modern gibbon that it is included in the Hylobatidæ. Thus even in these early times the anthropoid apes were already undergoing rapid differentiation

It is generally conceived that man arose in Miocene times from a *Dryopithecus* stock which also gave rise to the modern African apes. Prof W K Gregory has shown that the human dentition was almost certainly derived from this type The human stock, however, has avoided modifications which are a necessary concomitant of brachiating habits, and it is improbable, therefore, that the direct ancestors of man practised brachiation to any considerable extent. The evidence suggests strongly that in the evolution of man the limbs attained to human proportions in advance of other parts of the human body In early types of man such as *Pithecanthropus* or *Sinanthropus*, while the skull and brain were astonishingly ape-like, the limb structure was closely comparable or even identical with that of *Homo sapiens*. The larger an animal becomes, the more difficult it is for that animal to adopt the upright posture, and hence the common ancestor of man and the apes must have been a comparatively small animal, that is, at a hylobatid rather than a giant anthropoid level.

This harmonises with the fact that the gibbon is the only animal which shows an erect bipedalism comparable with that of man The strikingly human characters of the large African apes must owe their origin to parallel evolution The general form of ancient types of man—*Pithecanthropus* and *Sinanthropus*—recalls the gibbon rather than the great apes If modern types of man did come into existence early in the Pleistocene, it is probable that the direct ancestors of man are to be found in the Miocene forms of *Dryopithecus*, already distinct from the line leading to the modern large anthropoid apes

The known remains of *Dryopithecus* are almost entirely limited to jaws and teeth, and it has been surmised that the skull was probably not unlike that of the African ape It may be, however, that future discoveries will show that it manifested characters shadowing in a much greater degree those of the Hominidæ If Schlosser's interpretation of the Eppelsheim femur as really belonging to *Dryopithecus* be correct, it indicates that *Dryopithecus* was much more adept in erect bipedalism than any of the great apes of to-day, and lends further support, therefore, to the conception that the precursors of the chimpanzee and gorilla set off on their own evolutionary adventures some considerable time before the dryopithecine precursors of man had come on the scene

Vitamin Standards

THE International Conference held in London in June 1931 under the auspices of the Permanent Commission on Biological Standardisation of the League of Nations Health Organisation recommended for international adoption standards and units for vitamins A, B_1, C and D, which were to be provisional for two years. As certain of the standard preparations were not available until 1932, the second Conference was postponed until 1934, when two years experience of the practical application of the standards would be available

The report of the second Conference, which was held in London in June 1934 under the chairmanship of Prof. E. Mellanby, has now been issued (*Quart. Bull. of the Health Organisation of the League of Nations*: Vol. 3, Extract No. 15; 1934). No change has been recommended in the standards for vitamins B_1 and D The former, which has perhaps proved the most satisfactory of all the standards recommended in 1931, is an adsorption product of the vitamin, extracted from rice polishings, on fuller's earth The unit is the activity of 10 mgm of the standard It was prepared in the Medical Laboratory, Batavia (Java) by the method of Seidell, as described by Jansen and Donath The standard for vitamin D, which was prepared at the National Institute for Medical Research, London, is a solution in oil of irradiated ergosterol The unit is the activity of 1 mgm of this solution, which has been found equal to that of 0·025 γ of crystalline vitamin D. It is recommended that when a new standard solution becomes necessary it should be replaced by a solution

of the pure crystalline material in olive oil, of such strength that 1 mgm. contains 0·025 γ

The Conference recommends that pure β-carotene be adopted as the standard for vitamin A, in place of the present standard, which is a mixture of the isomers of carotene The value of the unit is unchanged and one such unit is contained in 0 6 γ of the new standard the old standard contained the same activity in 1 0 γ The standard preparation is to be issued in solution in a vegetable oil, in which it has been shown that it does not lose colour on incubation in the presence of air at 37° C for 7 days, the strength of the solution being such that 1 gm contains 500 units, or 300 γ of β-carotene The Conference report states that it has been found that measurement of the coefficient of absorption at 3280 A affords a reliable method for measuring the vitamin A content of liver oils and concentrates, and that the value obtained for $E^{1\ \text{per cent}}_{1\ \text{cm}}$ 3280 A can be converted into a figure representing units per gram by multiplying by the factor 1,600 This figure is the average of a series of comparative and independent tests on the unsaponifiable fractions of liver oils and on concentrates of high potency

For vitamin C the Conference recommends the adoption of *l*-ascorbic acid as standard, the unit being the activity of 0 05 mgm of the pure substance. (The previous standard was lemon juice, one unit being contained in 0 1 c c it has since been found that the potency of lemon juice varies, but the adoption of the new standard does not involve any significant change in the value of the unit) It was decided to ask the Institute of Medical Chemistry, Szeged, through Prof A Szent Györgyi, to prepare a batch of 500 gm of the standard and to ask Prof W. N Haworth to co-operate in controlling its purity

Among the subjects suggested for future work are the provision of a sample of cod liver oil as a subsidiary standard of reference for vitamins A and D and the investigation of the anomalous action on certain species of different sources of vitamin D

All the standards are kept at the National Institute for Medical Research, London, acting for this purpose as the central laboratory on behalf of the Health Organisation of the League of Nations

University and Educational Intelligence

CAMBRIDGE —The General Board recommends that the following additional University teaching offices be established : (*a*) an assistant directorship of research in the Faculty of Economics and Politics, (*b*) an assistant directorship of research in colloid science, (*c*) a University lectureship in the Department of Mineralogy and Petrology ; (*d*) a University demonstratorship in agricultural engineering (subject to financial provision being made by the Ministry of Agriculture and Fisheries); (*e*) two University lectureships in the Department of Pathology, (*f*) a University lectureship in experimental psychology ; (*g*) a readership in industrial psychology (subject to the provision by the Medical Research Council of the stipend and pension contribution) ; (*h*) an assistant directorship of research in industrial psychology (subject to the provision by the Medical Research Council of the stipend and pension contribution)

EDINBURGH : On the recommendation of the Senatus, the Court has approved of the establishment of a Sharpey-Schafer lectureship in physiology, a fund for the endowment of this lectureship having been contributed by pupils and friends of Sir Edward Sharpey-Schafer The first of the lectures, to be given biennially, will be delivered in the coming summer term

LONDON —The Buckinghamshire County Council has decided to make a grant of £5,000, payable over ten years, towards the erection of new buildings in Bloomsbury

A grant of £2,000 has been made by the Pilgrim Trustees to the London School of Economics towards central expenditure on the Land Utilisation Survey. The grant, which is for staff salaries and the preparation of the report on the Survey, is estimated to cover the cost of completing the Survey as far as central expenditure is concerned. Local bodies and others are subscribing to local expenditure, and it is hoped that sufficient additional contributions from these sources will be obtained to complete the total cost of the work The Pilgrim Trustees have further given valuable assistance to the Survey by setting aside a sum of £1,000 which can be drawn upon as required by the London School of Economics to secure the continuance of the publication of the maps This sum is to be repaid by the School from the publication account of the Survey

Science News a Century Ago

Walker's Eidouranion

"The Strand Theatre," said *The Times* of March 31, 1835, "from which Thalia and Melpomene have been banished by the Lord Chamberlain, has during Lent become the residence of Urania. Mr Walker, the well known popular lecturer, and perhaps the original lecturer, on the motion of the heavenly bodies and the phenomena of the planets, has commenced his very interesting lectures at this house. His lectures, and the reputation he has deservedly acquired by them, his apparatus and machinery, are so well known to almost all persons, that there is no need of giving a further description of them. They are in their contrivance elaborate and complex, but the illustration which they afford of the subject which he discusses is at once simple and intelligible The lecturer himself enters into his subject with a spirit of inquiry, and an earnestness of endeavour to familiarize science, which are very refreshing to those whose attempts at gaining information have been chilled by the technical formality of more stately teachers . At a time when the theatres are closed against dramatic performances the public cannot do better than devote a few hours to the acquirement of the scientific knowledge which these lectures, and similar lectures, convey and there can be little doubt that to the younger branches of the community they will convey that information to which young persons are exceedingly averse, unless it is conveyed in such a manner as to excite attention without distracting the understanding and wearying the patience " The lecturer was presumably Deane Franklin Walker (1778–1865) who, like his father Adam Walker (1731 ?–1821), lectured on science at Eton and Harrow and other public schools.

The Tides of the United Kingdom

On April 2, 1835, Whewell read a paper to the Royal Society entitled "On the Results of Tide

Observations, made in June 1834, at the Coast-Guard Stations in Great Britain and Ireland". Through representations made by Whewell, orders had been given for simultaneous observations of the tides at all the stations of the Preventive Service on the coasts of England, Scotland and Ireland from June 7 until June 22, 1834. The observations were sent to the Admiralty, and a part of them had been reduced From them Whewell had been able to deduce many important inferences. He found that the tides in question were not affected by any general irregularity having its origin in distant sources, but only by such causes as were merely local, and that therefore the tides admitted of exact determination with the aid of local meteorological corrections. The curves expressing the tides at high-water presented a very satisfactory agreement with theory A diurnal difference in the height of the tides, he said, manifests itself with remarkable constancy along a large portion of the coast under consideration The tide hour appeared to vary rapidly in rounding the main promontories on the coast, and very slowly in passing along the shores of the intervening bays, so that the co tidal lines are brought close together in the former cases, and in the latter run along nearly parallel to the shore, circumstances which would account for comparative differences of level and of corresponding velocities in the tide stream

Theories of Electricity

Prof William Ritchie (1790 1837), after being a schoolmaster in Scotland, went to Paris, where he studied under Thenard, Gay Lussac and Biot In 1829 he became professor of natural philosophy at the Royal Institution, and three years later was given a similar post in the University of London On April 3, 1835, he gave a lecture at the Royal Institution on the "Comparison of the two Theories of Electricity" The first of these theories, he explained, supposed that electrical phenomena depended upon the existence of a fluid universally diffused through matter and space, the particles of which repel each other inversely as the square of the distances If we abstract a portion of this fluid from a body, the latter becomes negatively electric, while if we add a portion, we produce the phenomena exhibited by positive electricity Another theory considered electricity to be a compound substance, consisting of two elements, positive and negative electricity None of the phenomena is observed until this fluid is decomposed, and then a portion of it goes to the attracted body Perhaps, said Prof Ritchie, the fluid may be the ether to which the phenomena of light seem attributable

The Dublin and Kingstown Railway

"The following is a statement," said the *Mechanics' Magazine* on April 4, 1835, "of the number of passengers, of different classes, conveyed along this railway during the first quarter of a year since it was opened, namely, from the 17th December 1834 to the 17th March 1835

1st Class fare,	1s each	10,008
2nd ditto	8d each	72,148
3rd ditto	6d. each	94,961
Total number of passengers		177,117

The whole of this immense number of passengers has been carried without the slightest accident of any sort. The receipts during the same period have amounted to £5,283 16s. 8d "

Societies and Academies

LONDON

Royal Society, March 21. D R. HARTREE and W. HARTREE Self-consistent field, with exchange, for beryllium. Fock's equations for the self-consistent field of an atom, including exchange effects, have been completely solved numerically for the normal state of neutral Be In connexion with the numerical calculations of energy values, a new check, depending on the direct calculation of the difference of energy values calculated using the solution of Fock's equations and using any other wave functions, is developed and applied The inclusion of the exchange terms has a small but appreciable effect on the (1*s*) wave function, which becomes more like that for the Be^{++} ion, and a considerable effect on the (2*s*) wave function, which contracts, and also becomes smaller near the origin compared to its maximum value These changes are qualitatively of a kind to bring calculated values of certain atomic properties into better accord with experiment. H R HULME, J McDOUGALL, R A BUCKINGHAM and R H FOWLER The photo electric absorption of X rays in heavy elements A method is developed for finding the photo-electric absorption coefficient for the *K* shell, σ_K The calculations are rigorous and are not subject to the restriction $Z \ll 137$, where Z is the atomic number Theoretically it is possible to apply the method for all values of $h\nu$, the energy of the quantum absorbed, but, as a considerable amount of numerical work is necessary, it is not practical for large values of $h\nu/mc^2$ Values of σ_K are given for $h\nu/mc^2 = 0\,693$ and 2 21 for elements with atomic numbers 26, 50 and 84 The values obtained do not differ much from those given by Hall, using a method which is discussed His expression has therefore been used for σ_A in the region $h\nu > 5mc^2$ and graphs have been constructed giving the photoelectric absorption *per atom* for various elements in the range $h\nu > 0\,7mc^2$ or $3\,4 \times 10^5$ e v The values obtained for lead are in excellent agreement with the experimental results as given by L. H Gray's empirical formula

DUBLIN

Royal Irish Academy, February 25 R Ó CINNÉIDE Some 2 4 derivatives of thiophene 2-Thiophene carboxylic acid condenses with *N*-methylolamides to form derivatives of the general formula 2 4 $HOOC\,C_4H_2S\,CH_2NHCOR$ These derivatives, on acid hydrolysis, give the amino acid 2 4 $HOOC\,C_4H_2S\,CH_2NH_2$, which can readily be oxidised to the known acid 2 4 $C_4H_2S.(COOH)_2$ The hydroxy acid 2.4.$HOOC\,C_4H_2S.CH_2OH$ can also be obtained from the above amino-acid.

is present. ADOLPH BOLLIGER: The volumetric microdetermination of picrolonic acid in organic picrolonates with methylene blue Picrolonic acid forms with methylene blue a compound which is sparingly soluble in water (less than 0·001 per cent), but fairly soluble in chloroform (0·16 per cent). Thus picrolonic acid is so far the most soluble *o*-nitrohydroxyl compound for titration with methylene blue. The technique of the titration is the same as that described for picric acid or other *o*-nitrophenols The end point is very sharp Varying amounts of 0 01*N* picrolonic acid could be recovered with an error not exceeding 0 2 per cent Further, the picrolonates of α-naphthylamin, piperidin and *p* toluidin were examined for their picrolonic acid content by the method described. P. M GAME: Geology of the Cudgegong district. This paper describes a bolt of country, 12–15 miles wide, extending south-eastwards from Mudgee for about 35 miles Upper Silurian and Middle and Upper Devonian strata are represented All three series are fossiliferous A great strike fault, following the Cudgegong valley, separates the Upper Silurian and Upper Devonian systems here, but elsewhere the three series are conformable with each other. They have been intruded by acid igneous types of the Kanimbla epoch, and are overlain unconformably by horizontal Kamilaroi and Triassic strata. Remnants of thick Tertiary sills and flows cap the highest hills, such as Mount Bocoble (sill), and Cumbermelon Mountain (flow) S C BAKER Testing a Lummer-Gehrcke interferometer, its use in a search for abnormality in the relative abundance of the isotopes of a special sample of mercury A cadmium-amalgam lamp of new design is described The relative intensities and half-value widths of the interference fringes of the cadmium red line were measured and compared with the theoretical values calculated from data of the apparatus Discrepancies are attributed to the experimental limitations The relative intensities of the hyperfine components of the green line emitted by two samples of mercury—one Australian, the other foreign—when excited by the high-frequency discharge differ by less than 2 per cent, which is within the limits of experimental error, so that there is no evidence of difference in the relative abundance of the isotopes of the two samples. F. A. COOMBS, W. McGLYNN and M B WELCH: The tannin content of a variety of *Acacia mollissima*, Willd. (4). A description is given of a variety of *Acacia mollissima*, black wattle, which occurs over a wide area of New South Wales Whilst the maximum tannin content found in seventeen analyses was found to be 51·5 per cent, the lowest was only 22·9 per cent It is evident that under favourable conditions this variety may yield a tan bark of high quality. M B WELCH The longitudinal variation of timber during seasoning (2) An examination was made of the longitudinal variation of some three hundred samples of a large number of different woods, in relationship to their densities While 66 per cent of the total samples swelled or remained stationary during drying from a green condition to the fibre saturation point, only 33 per cent behaved similarly from the fibre saturation point to an air-dry condition In general, woods of low density showed the greatest tendency to swell and heavy woods were more prone to remain stationary, during the initial drying period. Below the fibre saturation point, light timbers showed the greatest liability to shrinkage and heavy woods were inclined to remain stationary or to swell.

The Peoples of Britain

AT the present time, when racial questions are very much in the air, the proposal of the Royal Anthropological Institute for promoting a survey of the racial characters of the inhabitants of Great Britain is more than opportune It meets an urgent need in scientific investigation , and, incidentally, it will fill a serious gap in the common fund of established fact which makes up the background of public opinion Public policy recently has become involved in the discussion of a number of intricate and technical problems, with the result that clear thinking and clear definition were never a more urgent necessity than they are to-day It is here that the assistance of the anthropologist is invoked The importation of the racial question into international and national relations has opened a way to biased interpretation and racial prejudice which a statement of the facts and their direct implications alone can dispel

It is disconcerting to the anthropologist, and also perhaps humiliating to the dignity of his science, to reflect that one of the earliest, if not the first, survey of racial characters on a nation-wide scale was the outcome of political animosity The story is sufficiently well-known, but is worth recalling After the siege of Paris in 1870, in which the Muséum National d'Histoire naturelle was damaged by shell-fire—a catastrophe which, it is to be feared, we should not now regard with a like degree of surprise—de Quatrefages, the French anthropologist, while deploring the outrage, implied that it was congruous with the behaviour to be expected of Prussians, whom he demonstrated to be akin to the Mongolian Finns and, as such, barbarian intruders into Europe Amid the storm of controversy this statement aroused, the German Government countered with an order that the hair- and eye-colour of 6,000,000 German school children should be examined in the expectation that the facts thus elicited would be a sufficient refutation of the scandal It is, however, not uninteresting to note that Prof F G Parsons, who measured a large number of German prisoners during the War, found that their heads were considerably broader than the officially accepted figures, these latter emphasising the length and consequently Nordic character of the German head

Any light which a survey of the physical characters of the British population might throw upon current theories of European racial distinction

would be incidental to, and implicated in, racial analysis of the material collected, rather than direct Yet understanding of the racial composition of the inhabitants of Britain must be dependent upon and must be brought into relation with the racial constituents of the population of Europe, with which, we know, it is historically connected In any event, the results of the survey must impart to public discussion a leaven of clear thinking, and at the same time reduce to a more correct proportion any arguments as to national cleavage on a racial basis which may be imported into political discussion It is fairly safe to anticipate that accurate knowledge of the facts will scarcely lend support to an exaggerated view of the importance of any one strain in a given population

Any such contributions to current thought, however, it may be repeated, must be regarded as a by-product of the proposed survey Its aim primarily will be to obtain a record of the facts relating to the population of Great Britain The need for this is sufficiently urgent The outline which appears in another column (p 530) of the attempts to promote an anthropometric survey of the British population, shows that it is now more than fifty years since any extended series of measurements of the people as a whole has been made. Individual observers have been at work up and down the country, more numerous perhaps than a summary reference would suggest, and studies have been made of special categories, such as university students, but these efforts have been unco-ordinated, and uniform methods have not been employed There have been important studies also of skeletal material, of which Prof F G. Parsons's examination of Saxon skulls aimed at being complete But of the earlier observations, it may be said generally, that they do not meet the requirements of modern methods of analysis, and often are not adequate for statistical treatment In some instances it was admitted at the time the measurements were first submitted for examination that their value had been impaired by the lack of training of the observer.

While the physical anthropologist is, therefore, in a position to put forward a strong plea for renewed activity in this branch of his science, activity which will both bring together such scattered material as is already available and will stand the test of modern standards of measurement, as well as extend it by fresh observations to a national survey, the needs of the student of British archæology are by no means to be overlooked The great advances in the study of British archæology during the last fifteen or twenty years have demonstrated that movements of culture and cultural changes in the prehistory of the British Isles can be demonstrated in far more refined detail and in far more complicated pattern than was ever dreamed in the theories of the broad cultural and racial movements of which our predecessors traced the ways For the decisive answer as to how far cultural distinctions correspond to racial movements—a correspondence which is often assumed—the archæologist must turn to the student of race, the physical anthropologist. Nor will the material for the reply be drawn exclusively from the skeletal material of past ages, for, as Prof H J Fleure has shown, the persistence of ancient racial characters in certain areas can be demonstrated with a certainty nearly beyond question This problem indeed is one of the most interesting upon which investigation may be expected to throw light Many years ago, Dr J Beddoe in a presidential address to the Anthropological Section of the British Association directed attention to the survival of pockets of the short dark population in areas otherwise predominantly tall and fair—he was speaking more particularly of his observations in the area of Bradford where the Association was then meeting As a germane issue, it will further be of moment to note how far it is possible to determine the persistence of type in the face of modern conditions of movement and of the contact of the population of areas once kept apart by difficulties of communication.

While it is not possible to specify the numerous problems upon which it may be expected that light will be thrown, it may be noted that a whole group of problems is connected with the trend of racial development, upon which it is at present possible to speak with some probability, but upon which a definitive verdict is desired Sir Arthur Keith, for example, has told us that he regards a nation as a race in process of formation, in other words, it is a unit of specialisation. Is there adequate evidence, as some would hold, that we in the British Isles are evolving out of the elements of our mixed physical heritage a special type differing from, though obviously related to, the racial strains of the European continent? Again, there is the change in the shape of the head. Prof Parsons maintains that the skulls of Londoners in the last two hundred and fifty years have

undergone a process of broadening Is this true of the country generally or a phenomenon confined to London only ? And in the latter event, is it due to the immigration of a broader strain or to other causes ?

Although not part of the function of a racial inquiry as such, on a strict interpretation, it is clear that any evidence which may bear upon changes in the physical characters of the population is of the greatest moment on national grounds, especially if it can be correlated with evidence of a standard of health and the like The investigations of Prof Fleure and his colleagues in Wales, which seek to link up racial characters with the incidence of disease and other factors of social significance, do more than justify an appeal for public assistance towards the cost of the survey, which will be not inconsiderable Indeed, in the eyes of some, such inquiries, of which the survey is an essential preliminary, justify a claim for Government assistance A knowledge of the physical characters of the population of Britain is of the greatest interest to science, but it should be beyond the need of argument to show that it is of no less moment to the State

Reviews

Geology and Mineral Wealth of Burma

(1) *The Geology of Burma* By Dr H L Chhibber, with Contributions by R Ramamirtham. Pp xxviii + 538 + 26 plates (London · Macmillan and Co , Ltd , 1934) 30*s* net

(2) *The Mineral Resources of Burma* By Dr H. L Chhibber. Pp xv + 320 + 10 plates (London Macmillan and Co , Ltd , 1934) 18*s* net

(1) THE need for a treatise on the geology of Burma has been felt for many years, not only by those interested particularly in that country, but also by geologists who study the earth's crust on broad structural lines, by palæobotanists and palæozoologists who trace the natural history of flora and fauna throughout geological ages on world-wide evidence, and by petrologists who correlate information from different petrographic provinces to enable them to establish generalisations of great importance with respect to the story of the rocks. The need has been greater in the case of Burma than almost any other portion of the globe, because that country is situated to the south and west of one of the most extensive parts of the earth's surface about which least is known geologically. Tibet, Mongolia and Siberia to the north, and Siam and China to the east, have never been surveyed by geologists, with the result that for many thousands of square miles in that part of the world, geological knowledge is scanty in the extreme and, unfortunately, likely to remain so for some generations. It thus becomes of the greatest importance to place on record the available geological data about the only part of this vast land-mass where geologists have for some years been at work.

An account of the geology of so extensive a country as Burma must necessarily be largely a compilation. A careful summary and critical analysis of the work of others by one who, like the author, is well-qualified for the task, is valuable in itself, but the importance of this volume is greatly enhanced by the fact that the author has himself surveyed geologically certain parts of the country, enabling him to correlate information from isolated areas and to give, for the first time, a general outline of the geology of most of the province, although there still remain important gaps, especially in some of the hill regions

The first three of the thirty-four chapters deal with physical features, river systems and lakes , chapters iv–ix with earthquakes, hot-springs, mud-volcanoes, denudation, limestone caves and the coast-line , chapters x–xxvi describe the geological formations from the Archean to Post-Tertiary deposits ; chapters xxvii–xxxii give an account of igneous activities and petrological descriptions and chemical analyses of various types of rocks ; chapter xxxiii gives a series of variation diagrams based on rock-analyses, and the final chapter contains much new information relating to the geotectonics of the country

The author, when recently in Great Britain, availed himself of the opportunity of consulting a number of eminent geologists on various branches of the subject, and was particularly fortunate in being able to incorporate two valuable appendixes, one on the correlation of the geology of Burma and Malaya specially written for this volume by J. B. Scrivenor, late director of the Geological Survey Department of the Federated Malay States, and the other on the correlation of the geology of Burma and Assam, by P Evans of the Burmah Oil Co.

The book is illustrated by twenty-three plates, thirty-seven figures and three geological maps in folder-form. A comprehensive, almost complete, list of references is added at the end of every chapter.

(2) Burma is one of the most important provinces of the Indian Empire as a source of minerals of economic importance, and with respect to petroleum, silver-lead-zinc ores, and tungsten ore it is the chief British producing country in the Far East Indeed, during the War, its mineral production was of extreme importance It supplied the Empire, for example, with most of the ore from which tungsten, needed for the manufacture of high-speed tools essential for munition purposes, was extracted Deposits carrying gold, ores of tin and other base-metals, are mined in the country, and coal of an inferior quality occurs extensively Its famous rubies and sapphires are still being mined, but on a considerably smaller scale than formerly, because of the success of their synthetic production

It was a wise decision on the part of the author not to include an account of these important mineralised areas in the volume dealing with the geology, but to publish it as a separate book Although the two subjects are complementary, large tracts of the country which are of geological interest contain no minerals of economic importance, these being very restricted in their distribution in Burma, as in most other countries Mining engineers and mining geologists will be thankful for a work which, within 320 pages, deals with most of the hitherto known areas of mineralisation in a province of growing importance in its mineral production

The first chapter describes the geological and geographical distribution of the mineral deposits with statistics of outputs for the period 1926–30 Figures for two later years could have been included The remaining fifteen chapters deal separately with the different mineral occurrences, that on petroleum being by Dr L Dudley Stamp.

Because of the gold boom, much attention is being given at present to the occurrence of this metal in Burma The chapter on gold, however, whilst containing useful and recent information, occupies only eight pages, which is out of proportion, for example, to the sixty-four pages devoted to the relatively less important mineral jadeite Those interested in the wide distribution of gold in this province will be well advised to consult the valuable article on this subject by Dr. Coggin Brown, published this year in the first two issues of the *Mining Magazine*

The book is illustrated by nine plates, thirteen figures, and a folder giving a sketch map showing the important mineral occurrences It is well indexed, and bibliographies are given at the end of each chapter

The format of the two volumes is all that could be desired.

W. R. JONES.

Faraday's Diary

Faraday's Diary being the various Philosophical Notes of Experimental Investigation made by Michael Faraday, D C L, F R S, during the Years 1820–1862 and bequeathed by him to the Royal Institution of Great Britain Now, by order of the Managers, printed and published for the first time, under the Editorial Supervision of Thomas Martin Vol 5 *Sept 6, 1847–Oct 17, 1851* Pp xiii + 456+2 plates (London: G Bell and Sons, Ltd, 1934) 7 vols, £12 12*s* 0*d* net

AT the opening of the period covered by this—the fifth volume of Faraday's Diary—Faraday was fifty-five years of age, and signs of that failure of memory which clouded his later years were increasing Thus, in the summer of 1847 we find, in a letter to Lord Auckland, complaints of giddiness, loss of memory and confusion So to his faithful correspondent, Schonbein, he writes enthusiastically concerning ozone, but takes shame to "say that I have not yet repeated the experiments, but my head has been so giddy that my doctors have absolutely forbidden me the pleasure of working and thinking for a while, and so I am constrained to go out of town, be a hermit, and take absolute rest" Two years later, we find him writing to Matteucci to the effect that "I have lately been working for full six weeks trying to procure results, and have indeed produced them, but they are all negative But the worst of it is that I find on looking back to my notes, that I ascertained all the same results experimentally eight or nine months ago, and had entirely forgotten them"

Illness and failure of memory combined make a sad handicap, nevertheless, Faraday's output of work—the rough notes of which fill more than four hundred and fifty pages of the published diary—was remarkably large, and in the fertile year 1850, he read no fewer than five papers before the Royal Society Over and above this he gave, during the period 1847–51, courses of lectures on the allied phenomena of chemical and electrical forces, on static electricity, the Juvenile Lectures on the chemical history of a candle, Christmas Lectures on the forces of matter, and a course of six lectures on "some points of domestic chemical philosophy—a fire, a candle, a lamp, a chimney, a kettle, ashes". These, with Friday Evening Discourses, ranging from Schönbein's ozone to De la Rue's envelope machinery, represent a volume of work which would do no discredit to Faraday's great powers, even at their heyday

Dominating the early part of this volume of the

Diary are the experiments on magnecrystallic action, initiated by a description of Plucker's experiments on crystals (he makes an odd occasional appearance in the Diary as Pluckner). In 1849–50 we have the record of the experiments on the relation of gravity to electricity, on diamagnetic action, on gases in the magnetic field, on magnetic conducting power and on atmospheric magnetism; the year 1851 provides the data for the twenty-eighth and twenty-ninth (the last) series of Experimental Researches, on lines of magnetic force and on the employment of the induced magneto-electric current as a test and measure of magnetic forces.

To this period belongs the introduction of the terms *paramagnetic* and *diamagnetic*, due to Whewell, who writes to Faraday in July 1850: "The purists would certainly object to the opposition of *ferro-magnetic* and *dia-magnetic* ... it would appear that the two classes of magnetic bodies are those which place their length *parallel* . . to the terrestrial magnetic lines, and those which place their length transverse to such lines. Keeping the preposition *dia* for the latter, the preposition *para* or *ana* might be used for the former. Perhaps *para* would be best, as the word *parallel* would be a technical memory for it."

It will be seen that the Diary shows little falling-away in the intrinsic interest of its contents. It is superfluous to add that this volume, in the matters of editing and of printing, preserves the high standard of its predecessors. A. F.

The Teaching of Geography

Memorandum on the Teaching of Geography. Issued by the Incorporated Association of Assistant Masters in Secondary Schools. Pp. xvi+418. (London: George Philip and Son, Ltd.; Liverpool: Philip, Son and Nephew, Ltd., 1935.) 7s. 6d.

THE established place which geography has taken in the educational curriculum during the last thirty years has been gained by a revolutionary change in the outlook of the subject. From a mere recital of place names and uncorrelated facts, disliked by both teacher and pupil, it has developed into a study of the interrelationships of various distributions on the earth's surface and their relation to human activity.

The time is opportune for this review of the scope and position of the subject, which has been made by a representative committee of teachers. In discussing the aim of the work, the committee stresses the value of geography as a unifying subject, correlating not only various scientific studies, but also giving a link between humanistic and scientific sides of the curriculum. While the utilitarian side of geography is not overlooked, the committee stresses rather the cultural aspect, inasmuch as geography properly taught gives a view of the world as a whole and provides a background for a true appreciation of local peculiarities and national aspirations. It deprecates the teaching of economic geography as apart from regional treatment of the world as giving a non-geographical bias. It might have added a warning against the tendency of many textbooks and some teachers to regard the world merely as a field for industrial exploitation.

After discussing a scheme of work for schools, in which the committee advocates the teaching of physical geography as incidental to human interests rather than as an end in itself, the necessity of noting historical factors in many geographical topics is pointed out, for example, the woollen industry, and thus providing the opportunity of linking history with geography. This is a more satisfactory plan than the attempt to teach historical geography by itself, which may lead to the pitfalls of over-generalisation and exaggeration of 'geographical control'.

In useful chapters on teaching methods and apparatus the value of the globe as correcting misconceptions due to flat maps is noted. Possibly more attention might have been given to the nature of wall maps and atlases, of which many produced for school use are crude and over-generalised. A list of books suitable for the school library is not intended to be exhaustive, but the inclusion of several might be criticised. In a discussion on the training of teachers, the value of travel is an important point raised. This is rightly said to be as necessary to teachers of geography as to teachers of modern languages, to whom it is generally conceded.

A long chapter on examinations contains many criticisms and suggestions that should be helpful to examiners who are conscious of the pitfalls which beset them. The committee believes in easy papers with a high standard of marking. It gives a cautious acceptance to the new style of paper which certain examination boards are now trying. These papers in their demand for factual knowledge and discouragement of critical answers destroy initiative and penalise the bright candidate at the expense of the dull one. The greater possibilities of standardising the marking of a number of examiners seems to be the chief, if not the only merit of this type of papers. Their acceptance would mark a distinct reversion to the old and non-educational aspect of geography. The volume concludes with a careful bibliography of geography teaching. R. N. R. B.

A Course of Psychology

The New Field of Psychology the Psychological Functions and their Government By Prof Madison Bentley. Pp xvi+439 (New York and London · D Appleton-Century Co, Inc, 1934) 12s. 6d net.

PROF MADISON BENTLEY has chosen an ambiguous and even a misleading title for his book To most people the phrase "the new field of psychology" will suggest a study of one or more of the many recent movements in psychological science. In fact, as all psychologists know, Dr. Bentley published a book called "The Field of Psychology" some time ago, and this volume is simply a very thorough revision of that.

The author now ceases to discuss anything in terms of 'mental' events, processes, or forms of existence, and writes only of functions. The functions of the living organism, he holds, can be studied in two ways as chemical and biological processes which run their course within the bodily organism itself, and as psychological processes which cannot apparently be very clearly defined, but all of which involve some direct interplay between the body and what goes on outside the body Psychological functions he considers to be of three main varieties, those which further *apprehending*, those which carry out *action*, and those which lead to *comprehension* All these are closely related to the physiological functions, and must be regarded as growing out of them, and as based upon them. With this general scheme he discusses all the usual questions raised in a functional psychology.

The book is a textbook, and appears to be intended to cover the requirements of an introductory but comprehensive course. It consists of printed lectures, and it has much of the discursiveness and illustrative character of the lecture form Students and teachers are likely to get a little weary of it before they have finished, and to look for some presentation more direct and condensed. But of course it is well informed, it is generally clear, and it has the high merit, in a general psychological textbook, of complete consistency

Dr Bentley has printed seventy pages of footnotes to his lectures. Both the teacher, and the student who already knows something of psychological investigations, will find these far and away the most interesting part of the work. It is here that the author discusses the views of other people, and indicates the sort of reading that he would wish his students to undertake His expositions are sometimes arresting, his criticisms usually exceedingly good and not by any means always the conventional ones, and his selected authorities excellently chosen.

Short Notices

Russian Sociology: a Contribution to the History of Sociological Thought and Theory By Dr. Julius F. Hecker. Pp. xvi+313. (London Chapman and Hall, Ltd., 1934) 8s. 6d net.

THE writings of nearly thirty social philosophers are reviewed and summarised by Dr. Hecker in this book, which is re-issued after nineteen years Its general tendency will soon be obvious to the reader, especially if he turns towards the latter part of the volume, but it should be observed at once that the review covers the work of many other thinkers than those belonging to the later phase of dialectical materialism So far as it does this, it both increases the value of the book and the ease of the reader.

True and interesting remarks flash out here and there, and one is always curious to see how the generally accepted facts of the modern industrial State are met by the abstract theorist, whether of the Lenin or any other school. Mikalovsky, for example (fl. 1842–1904), said quite truly that, "Atrophy of the physical or the mental characteristics of man is possible through social or economic subdivision of labour". Bogdanov, the later and more purely theoretical writer (fl. 1873–1928), suggests that this may be corrected, "for the further increase in the complexity of machinery and the growing intelligence of the workers will eventually remove the final vestige of specialization Organizer and worker will merge into one"—a cryptic remark akin to the still more famous Marxian dogma that action and thought are identical. More definite is Bogdanov's criticism of the Marxian doctrine that the ruling class owed its position to the ownership of the means of production; Bogdanov would find it rather in the power of organisation. He is also the first exponent of 'teetology', or 'organisation-science', claiming for man the power to organise the "outer forces of nature, as well as human forces and experience itself". Here is the philosophy of a national plan in its germinal and most general form. The result of such organisation, especially in its Russian shape, we are all awaiting with interest; that it can contain much of the personal liberty which so many of these writers so ardently desire, is the most doubtful point. F. S. M

Geologic Structures. By Bailey Willis and Robin Willis Third edition, revised. Pp. xviii+544 (New York and London: McGraw-Hill Book Co, Inc., 1934.) 24s. net.

THIS book was first published in 1923 and a second edition appeared in 1929. In the third and latest edition the text has been completely rewritten and rearranged, while some fifty additional maps and

figures have been added As a result, the value of the book has been considerably enhanced, and in its new form it is undoubtedly the most exhaustive treatise on structural geology in the English language

The subject is treated from a descriptive and analytical point of view and there is a conspicuous absence of the confusing mass of theory and hypothesis with which the literature of tectonics is so overburdened The descriptive portion of the book is preceded by a discussion of the fundamental mechanical principles involved in the deformation of rock masses The description of each type of structure (folding, faulting, etc) is followed directly by a detailed analysis of the stresses and strains involved in its production

New chapters have been added on "The Physiographic Expression of Structure" and on "Practical Problems", while the section dealing with the wider problems of earth dynamics has been completely rewritten and affords an excellent account of modern views concerning the nature, age, constitution and physical and thermal state of the earth.

Although the book is of a detailed and systematic nature it is equally suited to the needs of the elementary student and the advanced worker, since the purely descriptive and the analytical sections respectively are treated separately, as indicated in the table of contents

A Hundred Years of Psychology, 1833-1933 By Prof J C Flugel (100 Years Series) Pp 384 (London Gerald Duckworth and Co, Ltd, 1933.) 15*s* net

THIS important book fills a very obvious gap in psychological literature, and will serve for many years as the most useful outline, although in no way sketchy, of psychology during its period of most energetic development

The author begins by giving a vivid picture of the position a hundred years ago, when Herbart's works had laid the foundation of psychology as a subject in its own right The next part surveys the period up to 1860, showing the rise of systematic, physiological and abnormal psychology During the next period, that is, up to 1900, the influence of the theory of evolution was felt, and psychology was applied to problems of the individual, the child and the animals; a period that experienced the activities of Spencer, Galton, Wm. James, Fechner, Helmholtz, Wundt, Charcot and Ribot, to mention only a few names, was clearly one of rapid development.

During the last thirty-three years there has been a tendency for schools to develop, each probably feeling much more in opposition to the others than will later prove to be the case The most outstanding characteristic of this period has been the fruitful application of psychology to education, industry and medicine

Unlike so many shorter histories, this book is interestingly written and should be read by all students of psychology, who will gain much from seeing their own speciality in perspective and treated in an unbiased way.

Geometrische Elektronenoptik: Grundlagen und Anwendungen Von E Bruche und O Scherzer Pp xii+332 (Berlin Julius Springer, 1934) 28 40 gold marks

ELECTRONS behave in many respects like light They may travel in straight lines, may be 'refracted' in electric or magnetic fields, may be focused as by a lens in suitably graded fields, or may be caused to produce interference patterns in properly disposed apparatus These are the matters which the authors of this book have chosen for their topic, and which they have elaborated with most praiseworthy attention to detail and extreme completeness of reference

Almost exactly the first half of the volume (164 pages) is devoted to the more mathematical and theoretical parts of the subject, while the second half (165 pages) is concerned with the more practical applications Commencing with the formal analogy between light waves and electrons, the authors proceed in logical manner to develop the theory of the motion of electrons in electric and magnetic fields, including a very complete mathematical discussion of 'electron lenses'. The experimental side of the subject is always kept in view

In the second half of the book the development of the original Braun tube to the present-day cathode ray oscillograph is first detailed, followed by a long chapter on the 'electron microscope' A very interesting set of comparison photographs of the same objects taken through the ordinary light microscope and the new electron microscope allow the reader to form his own conclusions about the present state of the new technique in relation to the old

Herbert Spencer's Sociology: a Study in the History of Social Theory, to which is appended a Bibliography of Spencer and his Work By Dr. J Rumney (Herbert Spencer's "Descriptive Sociology", continued by his Trustees) (Published for Herbert Spencer's Trustees) Pp xvi+357 (London: Williams and Norgate, Ltd, 1934) 10*s*. 6*d*. net.

THE winding up of the trust created under the will of Herbert Spencer for the publication of sociological material relating to the less advanced societies has been fittingly marked by the Trustees in the publication of this account of Herbert Spencer's sociological work Dr. Rumney, to whom they entrusted the task, has wisely not confined himself to a summary of Spencer's theories, but has analysed them critically in the light of modern developments in theory and method

Spencer has not received a very cordial welcome in academic circles, and it will perhaps come as a surprise to many who have not an extensive acquaintance at first hand with his writings to find how well they stand the test Dr. Rumney finds the main ground of criticism in the attention given to structure rather than function and in the neglect of modern or civilised societies in favour of primitive or archaic forms. The explanation of the latter failing, as he points out, is that in the days in which Spencer was working it was erroneously believed that the 'savage society is the simpler—a fallacy exposed by modern research

Mathematical Biophysics

By N RASHEVSKY, Department of Physiology, University of Chicago

THE application of physico-mathematical methods to biology has been advocated now and again by scientific workers, but until recently no systematic attempt to create a mathematical biology has been made, and the advocates of this 'science to come' have confined themselves to outlining the possibilities of such an approach True, there is a wealth of literature on the application of mathematical statistics to various biological phenomena, but the whole of this field of research lacks almost completely the physical point of view General physics is accepted as of paramount importance in the study of biological phenomena, the application of physical methods has already resulted in important biological discoveries But most of this application is restricted to the use of physical apparatus in biological experiment, and very little attempt has been made to gain an insight into the physico-chemical basis of life, similar to the fundamental insight of the physicist into the intimate details of atomic phenomena Such an insight is possible only by mathematical analysis, for our experiments do not and cannot reveal those hidden fundamental properties of Nature It is through mathematical analysis that we must *infer*, from the wealth of known, relatively coarse facts, to the much finer, not directly accessible fundamentals The greatest advances of modern physics are due to such men as Einstein, Bohr, Heisenberg, Dirac, who unravel the mysteries of the physical universe by the power of their thought, using mathematics as their tool

The objection has been frequently raised that mathematical methods, however useful in physical science, are inapplicable to biology, because of the tremendous complexity of biological phenomena But this argument should really be used in favour of, rather than against, the application of mathematics to biology A simple phenomenon can be understood by mere 'inspection', but it requires mathematical analysis to see through a complex system. The main thing is to apply mathematics methodologically correctly, by first studying abstract, over-simplified cases, which may even perhaps have no counterpart in reality Afterwards the various complexities of the case have to be taken into account gradually, as second, third and higher approximations. This use of abstract conceptions in the beginning is *the* characteristic of the physico-mathematical method Violation of this rule, and all attempts to start with actual cases in all their complexity, result in failure and have contributed to a sceptical attitude towards mathematical methods*

The following brief review of my own researches in mathematical biophysics may serve to illustrate the fruitfulness of a mathematical approach to this field

The fundamental living unit is the cell, hence it is with the study of a cell that we must begin But, faithful to our rule, we must start with a mathematical description not of any given type of actual cell, but of an abstract concept of a cell Not only are there innumerable varieties of cells, but also no two cells are quite alike They differ in size and structure and chemical composition Most of them possess a nucleus, some have several, others have none Some cells consume oxygen, some not Some metabolise one type of substance, others a different type If we discard all such properties of a cell as are not common to absolutely *all* cells, we arrive at the following definition of a cell, which holds for *all* cells whatsoever and which we take as defining our abstract conception of a cell.

A cell is a small liquid or semi-liquid system, in which physico-chemical reactions are taking place, so that some substances enter into it from the surrounding medium and are transformed, through those reactions, into other substances Some of these other substances remain within the system, causing it to increase in size; some diffuse outwards

Such a system is no longer so complex as to forbid any application of mathematical analysis, and we shall proceed to investigate mathematically various properties of such systems, or in other words, various consequences of the above definition

At a first glance not much can be done with such a general definition, but actual analysis shows quite the opposite As in geometry extremely simple axioms and definitions lead us to very complex propositions by reasoning, so will the same mathematical reasoning lead to important conclusions from the above definition of the cell[1]

First of all, it is easily demonstrated that whenever a system consumes or absorbs any kind of substance in solution in the surrounding medium, the concentration of this substance will not remain uniform, either in the system itself, or in the surrounding medium The concentration outside of the system will have a gradient towards the system. in the system itself there will be a

* Cf my article in "Philosophy of Science", 1, 176, 1934

gradient from the periphery towards the inside The reverse holds true whenever the system produces a substance which diffuses outwards into the *milieu externe*. The concentration will be greatest inside, and will decrease towards the periphery, and will then further decrease with increasing distance from the system The exact variation of the concentrations from point to point will depend on a number of factors, such as the size and shape of the system, the diffusion constants inside and outside, the permeability of the boundary, the type of reaction producing the gradient, etc But whenever a reaction producing or absorbing a substance takes place in the system, *as is always the case with a living cell*, such gradients of concentration are present.

Any dissolved substance produces an osmotic pressure, which for dilute solutions is proportional to the concentration of the solute, hence, whenever concentration gradients are present, they result in non-uniformity of osmotic pressure This in its turn results in forces, acting on each element of volume, and proportional to the gradients of pressure. Thus the very general and simple fact that *every cell metabolises* leads to the existence of a system of forces within and without the cell Like the gradients of concentration, the exact distribution of these forces will vary from case to case; but they are always there

Having thus deduced the existence of these forces, we must now investigate their possible effects To this end we must investigate various possible cases, which open up an unexplored field to the mathematician.

We start with the simple case of a spherical homogeneous cell, which either absorbs or produces some substance at a constant rate per unit volume: this rate being independent of the concentration of the substance. The distribution of concentrations within and without the cell has in this case a spherical symmetry and can be easily calculated the resultant force will be *zero* But things are different if the cell is slightly deformed from its spherical shape Mathematical investigation of the forces produced by such a deformed cell shows that, for substances absorbed by the cell, the forces are such as tend to restore the spherical shape; but for substances which are produced by the cell, the forces are such that they tend to increase the departure from the spherical and to *divide* the cell into smaller ones. Since in an actual cell substances are both produced and absorbed, the net result will depend on which forces prevail. This, again, is determined by various physical constants of the cell, the rates of reaction, etc.

Let us consider the more interesting case, when the *dividing* forces prevail. It can be shown that even in this case the cell will only become unstable and divide spontaneously when its size is greater than a certain critical value, for when the cell is below that size, surface tension, which opposes division, always prevails This critical size can be calculated in terms of the above-mentioned constants of the cell Although we do not know these constants with any accuracy, we have a fair knowledge of their order of magnitude, and can estimate the order of magnitude of the critical size at which a cell will divide, if it divides at all The sizes thus calculated happen to be the same as the sizes of actual living cells[2] We thus see that, merely by virtue of its metabolism, every cell contains in itself factors which may cause its division into two, whensoever in the course of its growth it comes to exceed a definite critical size The half-cells grow on until they in turn divide, and so on

As our next step, we must consider more complex cases of cells consisting of two phases, nucleus and cytoplasm The mathematical treatment here becomes much more complicated, but the general results remain the same

A further step leads us to non-spherical cells. At a first glance the existence of free, non-supported, liquid systems with a non-spherical shape sounds like nonsense, since we know from the laws of capillarity that in such a case the only stable shape of equilibrium is a sphere But this holds true only when forces other than a *constant* surface tension are absent Now, the presence of concentration gradients produces non-uniformities in the surface tension of the cell, this modifies the situation and makes non-spherical shapes of equilibria possible But those non-spherical shapes are possible *only* so long as the cell metabolises, as soon as the cell dies its metabolism stops, the gradients disappear and the cell assumes a spherical shape An illustration of this is found in many unicellular organisms, which possess oblong and sometimes eccentric shapes during life, but round up after death[3]

We have seen that the forces discussed above do not always produce division of the cell In such a case, however, a cell will not grow indefinitely As it increases its specific surface decreases, and the relative rate of growth decreases too A stage will be reached when anabolism just balances katabolism, and no further growth will result

The osmotic forces are not the only ones produced by concentration gradients. Other forces, due to attraction between various molecules, enter into play whenever concentration gradients are present. These forces may be of opposite sign to the osmotic ones Taking them into account makes the whole picture much more complex, but

the general conclusions remain as given above. We see that our apparently simple definition of a cell necessarily implies a complexity reminding one of the actual conditions in biological systems ![6]

An objection has been raised to all the above considerations that, in actual cells, protoplasmic streamings are often observed, which should stir the interior of the cell and even out the concentration gradients This objection is based on fallacy. Not only does the existence of protoplasmic streaming constitute no argument against the existence of gradients, but it is a positive proof for their existence Where there are streamings, there are the forces which produce them , and if everything were homogeneous, no such forces could be produced It is true that the occurrence of streamings will modify the distribution of forces, and so far this complication has not been taken into account , it is one of the next problems on our programme. It has been already suggested that such a further generalisation of the theory may throw light on the mechanism of locomotion in the Protozoa

Thus far we have been considering the effect of the forces produced by the cell on the cell itself, but the concentration gradients outside the cell result also in forces between one cell and another All those forces being of the same origin, there is a close relation between them Whenever we have an aggregate of cells in which the dividing factors prevail, they will repel each other On the other hand, when the 'restoring' factors prevail, cells attract each other. Of all cells, the neurones have most completely lost their property of dividing ; we should expect forces of attraction between them. Indeed the existence of such forces has been inferred by a number of neurologists, notably Ariens Kappers and Ramon y Cajal, from various observations The peculiar irregularity in shape of the neurones and the existence of a great number of interneuronic connexions is also to be accounted for by those forces. It has been suggested that a formation of new anatomical connexions between neurones may be the cause of conditioned reflexes and learning. Calculation shows that the above forces may account for it. Under certain conditions they will produce an actual new connexion in a very small fraction of a second.

This leads us towards a mathematical theory of nervous functions. We find that, under very general conditions, aggregates of cells such as are studied above will possess many properties characteristic of the brain. These include differential discrimination of spatial and temporal patterns by learning, and what is known in psychology as 'Gestalt-transposition' For details we must refer to the original papers[4]

Finally, the theory of intercellular forces has been applied to the form of cellular aggregates, forming multicellular organisms It has been shown that those forces account in a general way for the various stages of embryonic development (blastula, gastrula, neurula), and for the gross features of the forms of various classes of animals[5]

Having thus started from a study of the most general properties of a cell, we arrive in a deductive, synthetic way at a possible understanding of such problems as "why we behave as we do" and "why we are shaped as we are"

We have not mentioned at all the 'mechanism-vitalism' controversy. The problems discussed here are entirely independent of its issue, if there be an issue[6]. Whether the present-day concepts of physics will prove sufficient to provide an exhaustive explanation of life, or whether new principles will be introduced in the future, the treatment of those problems will of necessity be mathematical, if it is to be exact and scientific and not to resolve itself into mere verbal disputes.

Much remains to be done, but there can be little doubt of the fruitfulness of this approach The further we proceed, the more difficult become the mathematics involved ; but the results compensate for all difficulties C. F Gauss, "rex mathematicorum", derived many an inspiration for his purely mathematical discoveries from the study of physical phenomena. The time has come when mathematicians may find their problems in the ever-inspiring realm of living Nature.

Racial Studies in Britain

THE proposals put forward by the Royal Anthropological Institute for an organised anthropometric survey of Great Britain (see NATURE, 135, 463, 1935) revives a project in anthropological research of which too little has been heard in recent years It is a project which has had a curiously chequered history ; and its fate up to the present has been less than is deserved both by its intrinsic merits and by the enthusiasm and strenuous efforts of those who, from time to time, have endeavoured to bring it to practical effect. The story covers more than half a century

of the comparatively short history of anthropology as a science.

The racial history of Britain begins in what is now called pre-history with the studies of prehistoric skeletal material by Barnard Davis, Thurnam and Rolleston From this emerged the concept of a racial succession of long-heads and broad-heads of the stone and bronze ages with the long-headed Saxons and intruding Danes as an overlying element in the building up of the population Even before the publication of Thurnam and Davis's "Crania Britannica" in 1865, Dr John Beddoe had been at work in the 'fifties, collecting particulars of hair- and eye-colour in Scotland, Ireland and England, which he was afterwards to utilise in his "Races of Britain" But the first organised attempt at measurement of the living on an extended scale was made by the Anthropometric Committee of the British Association which reported in 1878 and succeeding years and in 1883 published a comprehensive final report, to which reference is sometimes made under the name of its secretary, C Roberts, who was responsible with Sir Rawson W Rawson for its compilation Notwithstanding the lapse of time, and in some instances the uncertainty of conclusions based upon insufficient data, this is still the standard of reference for any comprehensive account of measurements of the living in the British Isles

Various attempts, mostly somewhat spasmodic, were made to keep alive the work of the Anthropometric Committee Francis Galton measured 10,000 individuals at the International Health Exhibition of 1884, and a laboratory which he instituted at the South Kensington Museum with an elaborate programme of observations was in existence for some years. From the Manchester meeting of the British Association in 1887 until the Nottingham meeting in 1893, measurements were taken of such of the members of the Association as visited a temporary laboratory set up at each meeting under the care of a committee which reported annually Other British Association Committees were appointed from time to time A committee on the measurement of children became a committee for the study of the abnormal and, acting in co-operation with a committee appointed by the International Congress of Hygiene of 1891, recorded the observation of 30,000 children in 1892–93 and helped to secure the special treatment of the defective child; while a committee to promote anthropometric measurements in schools collected a certain amount of information, aroused some enthusiasm, but failed to initiate any general or extended action. Anthropometric observation also formed part of the extensive programme of a committee for the ethnographic survey of Great Britain appointed in 1892, which published five reports between that date and 1899, when it ceased to exist in favour of a proposal for an Ethnographic Bureau for Great Britain

Following this, the most serious effort in promoting anthropometric research was made early in the twentieth century by another Anthropometric Committee of the British Association appointed in 1902, which, although it did not carry out measurements on the living as was originally intended, nevertheless had an important influence on the further development of anthropometric observation This it achieved in the first place by drawing up under the chairmanship of D J Cunningham a code of instructions for anthropometric measurement, which, whatever its defects may have appeared to be to a later generation, secured the standardisation of a technique which was in advance of that of its day, and secondly by its efforts, and more particularly the efforts of individual members of the committee, to secure the recognition of an anthropometric survey of the inhabitants of Britain as a work of national importance, which should be supported by a subvention or even undertaken as a national charge

In the latter of these two activities of the Committee one member was indefatigable This was John Gray, its secretary throughout the whole of its existence A native of Aberdeenshire, he had taken up anthropometric work in the 'nineties, when he used to visit the fairs and other countryside gatherings in Buchan and record the physical measurements and characters of those who attended them His early contributions to anthropometric research were studies of the material thus obtained, which were submitted to the Buchan Field Club In this work he was soon joined by Mr J F Tocher, then of Peterhead, who made an ethnographical study of the school children of Buchan, which was also communicated to the Field Club. This work had one important consequence It brought the two men into touch with Sir William Turner, himself a famous craniologist and then professor of anatomy in the University of Edinburgh, through whose influence they were able to obtain financial assistance for their further work of anthropometric survey, one outcome of which was the important and authoritative study of the physical characters of the inmates of the asylums of Scotland.

It is not so much Gray's work as a persistent measurer of heads on all occasions, suitable or otherwise, or his ingenuity in devising 'fool-proof' anthropometric instruments, with which we are concerned here, as with his unobtrusive but determined and unceasing efforts to secure public recognition of the value of anthropometry, more

especially in its application to the population problem of Britain A word, however, must be spared for his early appreciation of the significance of biometric methods in anthropology. Like C. S Myers, whose paper on "The Future of Anthropometry" in 1903 has been regarded as a landmark, he recognised that much early work in physical anthropology was vitiated by the insufficiency of the data on which its conclusions were based, and advocated the employment, and himself consistently employed, sound statistical methods on the lines of Prof Karl Pearson's work, in the critical treatment of the data of the observer

It is not proposed here to attempt an examination of the contribution of the biometric school to the racial history of the British population, of which a brilliant example has recently come from the pen of Dr G M Morant For one reason it stands somewhat outside the movement now under consideration, though, it is to be judged, under the present proposals of the Royal Anthropological Institute, a more or less complete fusion of material from both sides will now take place

At about the time of the appointment of the last-named of the Anthropometric Committees of the British Association mentioned above, the people of Great Britain were much alarmed, so far as was to be gauged from the daily Press, by the alleged fact of a serious physical deterioration in the population and a marked inferiority of development among the children of the less well-to-do in the community. In part this was an aftermath of the Boer War, not unconnected with difficulties in recruiting for the Army Largely as a result of newspaper agitation, an Inter-Departmental Committee was set up to inquire into the matter Among those invited to give evidence before this Committee were several anthropologists, including D J Cunningham, chairman of the Anthropometric Committee and by now professor of anatomy in the University of Edinburgh

The Inter-Departmental Committee issued its report in 1904 Almost immediately afterwards the British Association met at Cambridge, where a full-dress discussion of the situation took place in Section H (Anthropology) under the presidency of Mr Henry Balfour, at which the Right Hon Arthur J. Balfour (afterwards Earl Balfour), then Prime Minister and president of the Association, was present. The most noteworthy features in the discussion were a doubt expressed by Arthur Balfour whether, judging from his own experience on his estate in Scotland, the conditions in rural areas were such as to conduce to the superiority in physique usually attributed to the countryman over the town population, if such superiority were a fact, and the conclusion, drawn from his observations of hair- and eye-colour, by Dr F. C. Shrubsall, that residence in urban areas favoured the dark as against the fair element in the population, and that this might possibly bear upon the incidence of disease, especially tuberculosis and cancer

The question raised in the discussion by the president of the Association served to emphasise the fact, already made patent in the report of the Inter-Departmental Committee, that there was a paucity of relevant measurement upon which any conclusion as to physique could be based Broadly stated, however, the conclusion of the Inter-Departmental Committee was that there was no evidence of organic, extensive or permanent physical deterioration in the population as a whole.

It was clear that this conclusion rested, for the most part, upon expressions of opinion, well-founded, no doubt, rather than upon the evidence of extended and comparative series of measurements These did not exist, except in so far as afforded by the British Association Committee's reports Other figures brought forward afforded no certain basis of comparison For children and adolescents, it is true, restricted series were available such as the measurements of the boys of Marlborough, where the annual anthropometric reports of Mr E Meyrick were a feature of the Field Club magazine for many years, and of Manchester Grammar School, but little was known of the working-class child-population.

Anthropologists were not slow to point out the defects of the report, and they emphasised the futility of discussion of groups of measurements from specific areas, or social groups, whether of adults or of children, unless a norm, or standard of normal development, or a series of such norms, had been established for the country as a whole and, more especially, for the various racial groups of which the population was composed So far as the measurement of children was concerned, the anthropologists joined forces with the educationists and every effort was made by deputation and otherwise to bring their views to the notice of the Government of the day. Arrangements were made for a joint discussion between the Anthropological and Educational Sections of the British Association to take place at the Leicester meeting in 1907, in which even that distinguished authority on the school child, Prof. J. Munsterberg, was prepared to join But when the meeting took place, its thunders had been stolen. In the course of the debate, Mr. Ramsay Macdonald, the leader of the Labour Party, who had promised to speak in support of a demand for Government action, was able to report that the previous night, or rather in the early hours of that morning, a Bill

for the medical inspection of school children had passed its third reading in the House of Commons For the success of this measure Sir Philip Magnus, the educationist, representative in Parliament of the University of London, had been largely responsible

The self-congratulations of the anthropologists on this measure were premature While recognising its value, and well aware of the benefit which, as time has shown, it was to confer on the people, when the Act came into operation, they noted with regret that no provision was made for anthropometric measurement as a general operation, and no attempt was made to set up a racial standard or standards against which to measure the abnormal or under-developed The results may be seen in some of the general conclusions put forward, especially in connexion with the effects of malnutrition, in early reports by medical officers who had not appreciated the finer points, patent to the anthropologist, in handling their material

From this time forward, the project of a nation-wide anthropometric survey, though not sinking entirely into oblivion, became less prominent It merged into larger proposals which the Royal Anthropological Institute contemplated promoting, while the untimely death of John Gray in 1912 and the outbreak of War helped to relegate it still further to the background in which stood the many desirable things which were to await more propitious times

In the meantime, also, active interest in anthropometric research had shifted to the regional surveys which were being carried out by individual workers, singly or in groups, and this up to the present has continued in the post-War period Of these surveys, it is not possible to refer in detail and mention must be confined to one or two, such as that carried out by Prof H J Fleure and his colleagues and pupils in Wales, of which an early report was presented at the Sheffield meeting of the British Association in 1910, the work of Prof F G. Parsons and his helpers in the Chilterns, which he has linked up with wider aspects of British ethnology especially in connexion with skeletal material from London and, more recently, Miss R M Fleming's continuous periodical measurements of school children in Wales, and her study of hybrids

The work carried out by Prof Fleure, or under his inspiration, is especially important in connexion with the proposal which has been put forward by the Royal Anthropological Institute Working with Aberystwyth as centre, Prof Fleure and his pupils have demonstrated the relation of racial history to a number of sociological and economic problems Of these investigations, not the least suggestive, from the point of view of practical politics, is the attempt to correlate, on scientific evidence above cavil, racial constitution and the incidence of disease

Apart from its practical applications, to which due weight must be given when public assistance is sought, to the anthropologist the most pregnant feature in Prof Fleure's work has been the demonstration of restricted areas in which has been found what appears to be the survival of a primitive—in some instances an extremely primitive—form among a population essentially modern in character In this his work links up with the more subtle interpretation of the prehistoric skeletal remains which began, perhaps, in the opening years of the century with Prof T H Bryce's survey of the prehistoric population of the short-cist graves of the Isle of Arran and the identification, soon afterwards, of the Beaker type, in the broad-headed skulls found in the neighbourhood of Aberdeen As Prof Fleure has again pointed out recently, the broad generalisations of racial history in Britain, however true at a certain level of thought, may mask rather than reveal facts of which a detailed view is needed In linking up the prehistoric data with those relating to the modern population, the survey which the Royal Anthropological Institute contemplates will carry on methods of study which, as received from the hands of Prof Fleure, have already had a profound effect in their application to racial problems in areas other than Wales

Obituary

PROF. J. J R. MACLEOD, F R.S.

BY the death after a long illness, on Saturday, March 16, of J J R Macleod, regius professor of physiology in the University of Aberdeen, medical science has lost an outstanding worker.

John James Rickard Macleod, a son of the manse, was born at Cluny, near Dunkeld, on September 6, 1876. He was educated at Aberdeen Grammar School and at the University of Aberdeen. He completed a distinguished undergraduate career by graduating M B , Ch B with honours in 1898, being awarded at the same time the Anderson Travelling Scholarship He worked for the next year in Germany, in the Institute of Physiology at Leipzig In 1900 he was appointed demonstrator in physiology at the London Hospital Medical College and in 1902 was promoted to be lecturer in biochemistry In 1901 he had been elected to the Mackinnon Scholarship of the Royal Society. He was appointed in 1903 to the chair of physiology at the Western Reserve University,

Cleveland, Ohio, where he remained until 1918, when he was elected to the chair of physiology at Toronto. During his later years at Cleveland, he was engaged in various duties arising directly out of the War of 1914–18. He also acted as professor of physiology at McGill University during part of the winter of 1916. After nine years at Toronto, he was appointed in 1928 to the regius professorship of physiology at Aberdeen, a post he was holding at his death

Macleod's main interest and occupation throughout his academic life was, of course, the metabolism of carbohydrate He published his first papers on experimental glycosuria in 1905, and between 1907 and 1917 a series of twelve papers under the general title of "Studies in Experimental Glycosuria" were published in the *American Journal of Physiology* as well as a series of eighteen papers between 1908 and 1921 dealing with other aspects of carbohydrate metabolism Macleod had thus a full knowledge of practically all the phases of this field of metabolism and the intimate parts played in it by the main tissues and organs of the body Thus equipped, he was both ready and willing in 1921 to put all the facilities of his laboratory and his unique knowledge of the subject at the disposal of the young investigator, F G Banting, who came to him with views on the isolation and preparation of the active principle of the internal secretion of the pancreas The intensive research work which followed, in which two other collaborators deserve honourable mention, J. B Collip and C. H. Best, culminated, as is well known, in the isolation of the active principle, insulin, from the islet tissue in such a pure form that it could be utilised as a medicament in practice The original idea which started this particular piece of fundamental research in the Toronto laboratory was certainly Banting's, but, without the facilities and co-operation provided by Macleod and others, it is very doubtful if the investigation would have reached such early fruition. The marvel, indeed, is that such clean-cut and final results were obtained so speedily The whole story is a testimonial to the value of team work ably directed to a single end

Macleod's activities in the field of carbohydrate metabolism received a fresh impetus with the discovery of insulin, and most of his later experimental work was directed towards the mode of action of the active principle His latest experiments were, in a way, a retrogression to the old ideas of Claude Bernard and his diabetic centre Macleod had taken up the investigation of the nervous control of glycogenesis in the liver and had obtained some interesting and suggestive results

Although Macleod's interests were centred on carbohydrate metabolism, he had from time to time carried out interesting investigations in other fields He had published papers either alone, or in collaboration with others, on caisson sickness, the control of breathing, ventilation, the biochemistry of carbamates, phosphorus of muscle and on many other miscellaneous subjects. He published, in addition to several books dealing with insulin and carbohydrate metabolism, an original textbook, characteristic of the man's outlook, "Physiology and Biochemistry in Modern Medicine", which is now in its seventh edition.

In 1923 Macleod, jointly with Banting, was awarded the Nobel Prize in Physiology and Medicine, and in the same year was elected a fellow of the Royal Society He was a fellow of the Royal Societies of Edinburgh and of Canada and a fellow of the Royal College of Physicians of London In 1928 he was appointed Vanuxem Lecturer in the University of Princeton and in 1933 Herter Lecturer in Johns Hopkins University He had been a member of the Medical Research Council (1929–33), past president of the Royal Canadian Institute (1925–26) and of the American Physiological Society (1922–23) He was a member of many learned societies, and held honorary degrees of several American universities as well as the LL D. of his own Alma Mater

As a man and a teacher Macleod was beloved by his friends and students alike. He was an excellent lecturer, lucid, happy and attractive. As a supervisor of research no one could have desired a more kindly and stimulating mentor He was ever willing to listen and to help, no matter how slow the pupil, provided the worker was in earnest As a man he was always happy, friendly and full of enthusiasm. He met every one with a cheery smile He was an optimist who refused to be depressed by ill fortune, and during the past four years he required all his optimism and cheeriness of spirit to stand up against his affliction No one could have faced with greater patience and a braver spirit the handicaps placed upon him

E P. C

PROF. R. O. HERZOG

PROF R. O HERZOG, who died at Zurich on February 4, made himself a name by discovering the microcrystalline structure of cellulose. He and Scherrer found it simultaneously and independently, when irradiating different kinds of cellulose fibres with X-rays This observation gave an enormous impetus to the investigation of fibres and organic substances of high molecular weight: twenty years ago, for example, no one would have dared to write down the structural formula of cellulose or to consider the rigidity of a macromolecule containing oxygen bridges, subjects of lively discussions at many scientific meetings nowadays. Herzog himself, then the head of the newly founded Kaiser Wilhelm Institut fur Faserstoffchemie at Berlin-Dahlem, was most active in promoting this development, and his vivid imagination played from the beginning with ideas which have materialised in recent years Michael Polanyi, Karl Weissenberg, Hermann Mark, Max Bergmann and Erich Schmid did research in his laboratory at Dahlem, and it was remarkable how successfully Herzog was able to collaborate with younger men.

The behaviour of substances of high molecular weight had always interested Herzog. He was one of the first to determine the diffusion constants of proteins and enzymes, and to become acquainted

with the anomalies of the diffusion of dyestuffs, his investigations concerning skin as an adsorbent, in correlation with the process of tanning, also deserve to be mentioned.

As to the technical work done by Herzog, his main efforts were concentrated on the literary side. He compiled a handbook of organic technology, and also edited a very comprehensive handbook series on the technology of textiles.

Herzog's intellect was keen, and his mind extremely versatile It was striking how quickly he discerned the possible answers to a given question; owing perhaps to an artistic trend in his nature, he seemed to prefer a subtle and surprising explanation to simpler and more probable ones, and was sometimes right in doing so

Born at Vienna on May 20, 1878, as the son of an influential journalist, Herzog took his degree at the University of Vienna in 1901 The following years he spent in Germany doing research work and commencing his academic career as *Privatdozent* at Karlsruhe in 1905 In 1912 he became professor of physiological chemistry at the German Technical Highschool in Prague, and from 1919 until 1933 he held the post at Berlin Dahlem referred to above He accepted in 1934 a professorship of chemical engineering at the University of Istanbul

Many friends deeply regret to have lost so prematurely a man of his inspiring personality.

H F

WE regret to announce the following deaths

Dr. Shepherd Dawson, principal lecturer in psychology, logic and ethics in Jordanhill Training College, Glasgow, known for his work on vision and statistical problems in psychology, on March 26

Dr Carl Duisberg, founder and chairman of the I G Farbenindustrie, known for his work in connexion with aniline dyes, on March 18, aged seventy-three years

Prof A Hantzsch, formerly professor of chemistry in the University of Leipzig, who was an honorary fellow of the Chemical Society, on March 14

Sir E Sharpey Schafer, F R S, emeritus professor of physiology in the University of Edinburgh, on March 29, aged eighty-five years

News and Views

Differential Analyser for the University of Manchester

THE important new calculating machine, known as a differential analyser, presented to the University of Manchester by its deputy treasurer, Mr Robert McDougall, and constructed by the Metropolitan-Vickers Electrical Co. Ltd., was opened on March 27 A distinguished gathering, presided over by the Earl of Crawford and Balcarres, Chancellor of the University, heard from Prof. D. R Hartree, under whose direction the machine has been built, an account of how it is constructed and what it will do Briefly, the object of this machine is the evaluation, by mechanical means, of solutions of ordinary differential equations; it is readily applicable to a very wide range of such equations, and in particular is not restricted to those which are linear. The original conception of such a machine was due to Lord Kelvin, and the first satisfactory working machine was designed and built by Dr V. Bush at the Massachusetts Institute of Technology; this machine is quite distinct from one for solving simultaneous algebraical equations, also designed by Dr Bush, of which mention has already been made in NATURE (Dec 8, 1934, p. 877).

PROF. HARTREE mentioned the wide range of problems in pure and applied science to which the differential analyser could be applied, and said that he hoped to see it used, not only for investigations in pure science, such as the problem of atomic structure in which he was particularly interested, but also to work of technical and industrial importance as well. He paid a warm tribute to Mr. McDougall's munificence in furnishing the University with this powerful and important research tool, to Dr Bush for his generous and friendly co-operation in its design, and to various members of the Metropolitan-Vickers Electrical Co Ltd., who had been concerned in its design and construction After brief speeches by Sir Kenneth Lee, who declared the machine 'open for business', Sir Henry Lyons, and Prof Bragg, those present descended to the basement of the Physics Laboratory where the machine has been erected, and saw a demonstration of the machine in operation.

Lord Bledisloe and Maori Studies

AMONG the many public-spirited acts which have marked Lord Bledisloe's tenure of the office of Governor General of New Zealand, few aroused more public enthusiasm than the gift to New Zealand by Lady Bledisloe and himself of the Waitangi Estate, the historic ground where the treaty between the British authorities and the Maoris was signed in 1840 To mark the ninety-fifth anniversary of the signing of the treaty, and to commemorate the gift of this land to the people of New Zealand, the New Zealand Numismatic Society, of which Lord Bledisloe is patron, has struck a medal in silver, bearing the head of Lord Bledisloe on the obverse, which was presented to him at a meeting of the Society held at Wellington on February 6 The presentation was made by the president of the Society, Prof J Rankine Brown In accepting the medal, Lord Bledisloe expressed the hope that the nationalisation of Waitangi would help to promote in New Zealand the sense of nationhood, and referred to the work of the first governors, Capt Hobson and Sir George Grey, "the great far-sighted pro-consul and racial pacificator". Lord Bledisloe went on to emphasise the

importance of Polynesian, and particularly Maori, studies He maintained that the white people should learn the language and appreciate to a greater extent the mental and spiritual outlook of the Maori people While he regretted that it is no longer true, as it was thirty years ago, that at least one third of the Legislature is acquainted with the Maori language and outlook, he hoped that improvement would come from the endowment left to promote knowledge of the manners, customs and language of the Polynesians by the late Prof Macmillan Brown, whose enlightened aspirations had given him personally immense encouragement

Recent Archæological Finds in Ireland

AN authoritative article on recent Irish excavations by Mr Sean F. O'Riordan, of the National Museum of Ireland, appears in the April number of *Discovery*. During the year 1934, the National Museum received an unusual number of accessions of exceptional interest as the result of casual discovery Among these were the remarkable gold gorget of about 700 B C from Co Clare, the bronze age wooden shield—only the second known—from Co Mayo, the fine Middle Bronze Age rapier from Co Tipperary and much noteworthy Viking material from Co Dublin The greatest advance in the study of Irish archæology, however, has been due to the participation of archæologists in carrying out the Government's scheme for unemployment This has made possible systematic investigation on an extended scale on an unprecedented number of sites No less than twelve excavations were carried out in various parts of the country, ranging in date of the period under investigation from post-glacial times to the fifteenth century A D The number of workmen engaged on individual sites in these operations varied from twelve on the smallest to fifty on the largest.

The results of the investigation of the sequence of events in post-glacial times at Ballybetagh are already well known, owing to the interest aroused by the pollen analysis, though the report is not yet complete Another investigation of wide general interest, although purely negative in result, is that in the cave of Kilgreany, Co Waterford Some years ago members of the Bristol Spelæological Society claimed to have found there human remains of palæolithic age The present investigation has not substantiated this, and evidence of palæolithic man in Ireland is still to be sought Questions of major interest are also solved at Cush, near Kilfinane, Co Limerick, where for the first time ring forts were found in a series of six, a souterrain was for the first time definitely dated so early as pre-Late Bronze Age, and the Irish town, previously not known before Viking times, was shown to have existed so far back as the Bronze Age

Major-General A. W. Greely

THE American explorer Major-General A. W. Greely, who has just reached the age of ninety-one years, is reported by *The Times* to have been awarded the Congressional Medal of Honour of the United States for heroism on his Arctic expedition of 1881–84. That expedition was the contribution of the United States to the International Polar Stations of 1882–83 Under Lieut Greely's leadership, three officers and nineteen men were landed in Discovery Harbour in Grant Land (Ellesmere Island). The main objects were meteorological and magnetical observations, but Lieuts Greely and Lockwood carried out extensive explorations in Grant and Grinnell Lands, and Lieut Lockwood made the northern record to lat 83° 24′ N The relief ship was prevented by ice from reaching the camp in 1882 and again in 1883 Lieut Greely then decided to retreat to the south with much depleted equipment and scanty stores Near Cape Sabine in Smith Sound, they passed their third winter Already scurvy had taken a heavy toll and the remaining men were scarcely able to hunt, fuel and food were practically exhausted when in June 1884 relief reached them in the *Thetis* Only seven men were alive, not one could walk without assistance and at the time there seemed little likelihood of any living long enough to reach an American port General Greely was awarded the Founder's Medal of the Royal Geographical Society in 1886 for the excellence of his Arctic work

Henry Fuseli (1741–1825)

A RENEWED interest in the work of the Swiss artist Henry Fuseli (1741–1825) is being taken at present through an exhibition of some of his paintings and drawings at Ryder Street, London, S W 1 Fuseli came to London at a time when Germany was anxious to establish channels of literary communication with England Among those whose acquaintance he cultivated was Johnson, the radical bookseller of St Paul's churchyard, where Priestley usually stayed when he came from the provinces to the metropolis Both Fuseli and Priestley were in holy orders occupied occasionally with pamphleteering and possessing considerable linguistic abilities In Thorpe's "History of Chemistry" is a portrait of Priestley delineated by Fuseli in which the discoverer of oxygen is depicted with more femininity of expression than is usually associated with such a free lance Fuseli became one of the 'lions' of London society and an indispensable guest at many a fashionable dinner table He was buried in St Paul's Cathedral between the graves of Opie and Reynolds

Professor of Astronomy at the Royal Institution

AT the general monthly meeting of the members of the Royal Institution, held on April 1, it was resolved to establish a professorship of astronomy Sir James Jeans was nominated, and in the event of his election at the ballot on May 7, will become the first professor of astronomy in the Institution. The last occasion when a new chair was created was the year 1863. This was for Dr. (afterwards Sir Edward) Frankland, who was elected to a separate professorship of chemistry while Faraday was still the Fullerian professor of chemistry. Frankland's professor-

ship lapsed, however, after Faraday's death The other 'elected' professorship in the Institution at the time, that of natural philosophy, had been established ten years earlier, and was not so short lived It was created for Tyndall when he went to the Institution in 1853, and since his retirement in 1887 has continued by election and re-election down to the present day Sir James Jeans has thus been nominated to the first new professorship to be established in the Royal Institution for some seventy years It is also the first chair of astronomy in the history of the Institution

Revision of Ordnance Survey Maps

DURING last autumn, the council of the Chartered Surveyors' Institution decided to press for an official inquiry into the present position of the maps and plans of the Ordnance Survey, and an article on the subject appeared in NATURE of November 3 (p 677) In reply to a question by Sir Francis Fremantle in the House of Commons on April 1, Mr Walter Elliot, Minister of Agriculture, said "A substantial addition has been made to the Ordnance Survey Estimates for 1935, and this will enable a beginning to be made in the way of overtaking arrears I propose, however, to refer to a Departmental Committee the whole question of the acceleration of the revision of Ordnance Survey maps and the preparation of plans for town and country planning I hope shortly to be able to announce the composition of the committee and its terms of reference"

Model of the *Rocket*

A FULL SIZE replica of the locomotive *Rocket*, as originally designed and constructed by Robert and George Stephenson, has now been acquired for the National Collections in the Science Museum, and will be unveiled by Mr L Hore-Belisha, Minister of Transport, at noon on April 11 The model has been made by Messrs Robert Stephenson and Co, the firm which built the original engine, and represents it, as nearly as possible, in form, materials and workmanship, as it originally appeared. The original engine was built to compete at the Rainhill Trials in October 1829, which was perhaps the most important event in early locomotive history The success of Stephenson and Booth's *Rocket*, which won the premium of £500 offered by the directors of the Liverpool and Manchester Railway for the most improved locomotive engine constructed in accordance with certain conditions, definitely proved the suitability of the locomotive as a means of general railway haulage, and showed that speeds hitherto unapproached could be attained. The engine was entered by George and Robert Stephenson and Henry Booth. Its success was mainly due to the adoption of the tubular boiler, which was suggested to George Stephenson by Booth While George Stephenson is popularly credited with the design of the *Rocket*, its actual construction, at Newcastle, was carried out by his son Robert, the father's time being fully occupied with the making of the railway itself.

Co-operation between the Chemical Societies of Great Britain

THERE has recently been circulated to all members of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry a draft agreement between the three Societies in regard to co-operation The adoption of the agreement is unanimously recommended by the Council of the Society of Chemical Industry and the draft agreement was published in *Chemistry and Industry* on March 15 The agreement provides for the establishment of a fund to be administered by a Chemical Council consisting of three members nominated by the Council of each Society, together with three representatives of industry, co opted in the first instance on the nomination of the Association of British Chemical Manufacturers The objects of the fund are the allocation of grants to the constituent bodies for the co ordination of scientific publications, promotion of research, maintenance of a library etc Complete freedom of action is reserved to each constituent body in respect of the matter it publishes The management of the library of the Chemical Society is delegated to a joint library committee, and contributions to the net annual maintenance expenditure are to be borne by the constituent bodies in proportion to their membership, with due allowance for overlap This involves, for example, an increase in the contribution of the Institute of Chemistry to £654 and from the Society of Chemical Industry to £448 The agreement is for seven years and thereafter to continue for successive periods of three years, subject to right of withdrawal on giving one year's notice at the end of any period If the agreement succeeds, it is anticipated that means of reducing subscriptions to the three organisations will be found

American Chemical Industry

THE American Chemical Society is holding in conjunction with its annual meeting in New York on April 22, what may prove to be the largest scientific assembly in history The object is to expound and commemorate the development of the American chemical industry since its foundation three hundred years ago by John Winthrop Jr, son of the pilgrim Governor of the Massachusetts Colony In 1633 he set up in Boston the first chemical laboratory and library in the United States, for which he imported apparatus, chemicals and chemical books, and two years later when he became the first colonial Governor of Connecticut, he mapped out a far-reaching programme of local industries including the production of salt, iron, potash, tar, black lead, saltpetre, medicines, copper, alum and other chemicals Some of these chemicals were made for local use; the chemicals of the forest were exported It was at Winthrop's suggestion that Massachusetts passed a law in 1642 requiring every town to collect manures to make saltpetre Chemical industry in the modern sense did not begin in the United States until 150 years later, when in 1792 the manufacture of sulphuric acid was commenced in Philadelphia by John Harrison.

SINCE that time, the American chemical industry has not ceased to expand In 1913-14 it produced 34 per cent by value - and much more by weight -of the world's chemical output, in 1923 24 this percentage had risen to 47 per cent At the Congress it will be shown how the infant industries have become the bulwark of national defence, the basis of modern industrial progress and the source of an ever growing percentage of national wealth The honorary chairman of the New York Committee is Mr Francis P Garvan, the presidents of the great chemical companies are co-operating with the Society At the chief symposium the outstanding addresses will be by T Midgley on "Chemical Developments in the next 100 years", and W B Bell on "National Planning and the Chemical Industries" In addition, Senator Harrison will discuss economic aspects of the chemical industries in general Mr Lammot du Pont will deal with chemistry's sociological results and Senator Wadsworth will consider its importance in national integrity The Congress will be divided into eighteen divisions ranging from foods to petroleum

Hydrogenation of Coal

A LECTURE by Dr Pier before the Technische literarische Gesellschaft, Berlin, on the hydrogenation of coal, possesses an unusual importance in view of present interest in this subject and also in German efforts at national self-sufficiency In Germany the first technical success was achieved in the hydrogenation of brown coal and tars produced therefrom For several years large quantities of petrol have been produced from brown coal at the Leuna works of the I G Farbenindustrie A G Since 1932, interest has been directed to corresponding treatment of bituminous coal in the Ludwigshafen works of the I.G Since last year, a plant capable of a daily throughput of 20 tons of coal has been working there, and it is the successful performance of this unit which forms the subject of Dr Pier's paper Actually, a somewhat similar plant has been in operation at the Billingham works of Imperial Chemical Industries, Ltd since 1930, and the large unit (500 tons daily) projected in 1933 will soon be brought into commission The results of the German tests leave no doubts as to its success

HYDROGENATION reactions may take several forms, for example, in liquid phase with coal or oil, and in vapour phase with more volatile liquids At Billingham the petrol is already being made from creosote oils in vapour phase units The patent rights in these processes are held by the International Hydrogenation Patent Co, and since 1931 experience and information in these processes have been pooled by the I.G., Imperial Chemical Industries, Standard Oil and Shell Oil Companies. Although the literature of coal hydrogenation on the experimental scale is large, information about the construction and performance of manufacturing units has not hitherto been disclosed, and this lends added importance to Dr Pier's paper. As a result of international co-operation for scientific and industrial purposes, the work stands in marked contrast to corresponding efforts in the political fields

Excavation of Norfolk 'Woodhenge'

ACCORDING to an announcement reported in *The Times* of March 29, preparations are being made by the Norfolk Research Committee, of which Mr Russell J Colman is president, to explore the site which, from its similarity to that on Salisbury Plain, has been called 'Woodhenge', at Arminghall, near Lakenham Baths, Norwich The existence of this circle was first ascertained by observation from the air by the Royal Air Force, and certain preliminary examinations carried out soon after revealed the character of the site, but no systematic or extended excavation has as yet been attempted The present operations will be under the supervision of Dr Grahame Clark, of Peterhouse, Cambridge, and secretary of the Fenland Exploration Committee, and Mr Rainbird Clark, honorary secretary of the Norfolk Research Committee The work will begin in August next and, it is hoped, will be completed when the British Association meets at Norwich in the following month

Jubilee of the Dublin Naturalists' Field Club

THE jubilee of the Dublin Naturalists' Field Club will be celebrated in Dublin on July 11-13 by a meeting of representative delegates from many of the natural history societies in Ireland and Great Britain, and probably from abroad Formed fifty years ago with Prof E Perceval Wright as its first president, the man mostly responsible for the initiation of the Dublin Naturalists' Field Club was its vice-president, Dr A C Haddon, the veteran anthropologist now at Cambridge The formation of the Irish Field Club in 1894 brought the Society into closer touch with other natural history bodies in Ireland, while in 1892 it was largely responsible for forming the old *Irish Naturalist* as a monthly journal for the scientific recording of its and other societies' proceedings Among the more notable workers of the Field Club in its history were G H Carpenter the entomologist and mammalogist, for many years its president, as at the Galway Field Club conference of 1895, Dr R Lloyd Praeger, its secretary in late Victorian times, who wrote the flora section of the British Association Handbook for its Dublin meeting of 1908, and David McArdle, of Glasnevin, who wrote the section on mosses and lichens in the same handbook Other prominent members of the Field Club in its early years were Prof T Johnson, its treasurer, Prof E. J. M M'Weeney of Dublin and Prof G F Fitzgerald of Trinity College

Twelfth International Congress of Zoology

IT is announced that the Twelfth International Congress of Zoology will be held at Lisbon on September 15-21 under the presidency of Prof A. Ricardo Jorge, professor in the Faculty of Sciences in the University of Lisbon, and director of the Zoological and Anthropological Department of the National

Museum of Natural History (Museum Bocage) His Excellency the President of the Portuguese Republic has consented to become Patron of the Congress, and the Portuguese Government has invited foreign countries to be represented by official delegates It has been provisionally arranged that the work of the Congress will be carried on in twelve sections, dealing respectively with (1) general zoology (including cytology and genetics), (2) embryology and the mechanics of development, (3) comparative anatomy, (4) physiology, (5) zoogeography and palæozoology (including ecology), (6) protozoology, (7) entomology, (8) invertebrates, (9) vertebrates, (10) parasitology, (11) applied zoology, (12) nomenclature Some of these sections may be subdivided if the need arises Among social events proposed are receptions by the President of the Republic, by other Ministers, by the Rector of the University, and by the municipality of Lisbon; and various excursions, including one to Madeira and the Azores to take place after the Congress, are contemplated. Special facilities as regards railway fares and hotel rates are being arranged for by the organising committee Zoologists desiring to take part in the Congress are requested to communicate with the president, Prof Arthur Ricardo Jorge, Director, Zoological and Anthropological Department, National Museum of Natural History, Lisbon, Portugal, from whom particulars can be obtained

The Strangeways Laboratory

THE Strangeways Research Laboratory was founded by the late Dr Strangeways in Cambridge twenty-one years ago A recent report by the trustees and director takes the opportunity of recalling the history of its foundation and development during this period, in addition to giving the usual account of the past year's work The building now used as the laboratory was originally equipped as a small hospital for the treatment and study of chronic arthritis, but Dr Strangeways soon became convinced that a more complete and fundamental knowledge of the processes of normal growth was an essential condition for real progress in the investigation of this and other diseased conditions The hospital therefore became a group of experimental laboratories devoted to the study of growth problems by the methods of artificial culture of tissues Dr Strangeways died in 1926 his principal collaborator, Dr Honor Fell, has acted as director since 1928 Since 1931, the Royal Society has made itself responsible for the director's stipend, by a fellowship from its Messel Research Fund. The Medical Research Council has made grants providing for the support of certain members of the staff and for general expenses of the work Grants have been made by the British Empire Cancer Campaign, by the Fitton Trust and by the Sir Halley Stewart Trust; and the laboratory has received voluntary subscriptions and donations, though both of these sources of income have varied widely from year to year. To enable the work of the laboratory to continue and to expand, an increase in the annual income is, however, required. During the past twenty one years, 84 persons have worked in the laboratory and 81 papers have been published. The research work of the laboratory is devoted to fundamental problems of normal and abnormal growth and the effects of different forms of radiation upon living cells, problems of immense importance to the successful treatment of tumours in human beings by X-ray and radium

A New Rotating Radio Beacon

A ROTATING loop type of radio beacon was developed in Great Britain several years ago, and two stations employing this arrangement are still in use in connexion with aerial and marine navigation The advantage of the system is that wireless bearings may be obtained at any receiving station merely with the aid of a stop watch or chronometer The use of such a chronometer is rendered unnecessary in a new type of rotating beacon, which is described in a paper by U Okada, published in the report of Radio Research in Japan of October 1934, vol 4, p 185 In this new system, a vertical loop transmitting aerial is used as previously, to give the usual 'figure of eight' radiation characteristic Instead of rotating this loop continuously, however, it is swung backwards and forwards about a vertical axis through an arc of 180°. During its movement the speed of rotation is uniform and equal to one revolution per minute The movement in each direction starts from a north and south position alternately, at each of which a characteristic morse signal is omitted This signal is then followed during the rotation of the loop by a succession of 90 dots, at the rate of 1 dot for every 2 By counting the number of dots from the starting point to the signal minimum, the bearing of the receiver from the transmitter may be calculated The additional observation taken with the loop moving in the reverse direction enables the midpoint of a broad minimum to be accurately determined Tests carried out in Japan on land and at sea have shown that an accuracy of observation of $\pm 6°$ was obtained at distances up to 46 km with an experimental beacon operating on a wave length of 950 m It is considered that by attention to details of the apparatus the maximum error could be reduced to 2°, which it is suggested is sufficient for most practical purposes

The 100-in. Mirror Aluminised

ACCORDING to Science Service, of Washington, D C, the 100-in mirror of the great telescope at Mount Wilson Observatory, Pasadena, California, has been aluminised It will be remembered that a new process has been developed within the past two or three years, by which coats of aluminium are placed upon glass mirrors by distillation *in vacuo* (NATURE, 134, 522, 1934) The aluminium coat presents several advantages over the usual silver coat, chemically deposited The aluminium coat is far more durable and resistant to tarnish, and possesses a superior reflectivity in the ultra-violet Many small mirrors have been successfully coated with aluminium in Great Britain It is expected that the new 200-in mirror will also receive an aluminium coat The

aluminium surface on the 100-in mirror is said to be perfect except for the silhouette of a moth in one corner of the large surface

Control of the Bed-Bug

AT the request of the Ministry of Health, the Medical Research Council has undertaken to promote further investigations into the health problem caused by the infestation of houses by the bed-bug, and has appointed the following special committee to advise and assist in this work . Prof. J. C G Ledingham (chairman), Prof. P A Buxton, Mr. C S Elton, Mr C R Kerwood, Dr John Macmillan, Dr G W. Monier-Williams, Prof J W Munro, Dr. P G Stock, Dr R E Stradling, Mr A W McKenny Hughes (secretary), British Museum (Natural History) On the recommendation of this Committee, grants have been made by the Council for research under the direction of Prof Buxton into the natural history of the bed-bug with reference to the conditions of its viability, and for research under the direction of Prof Munro into chemical methods for its destruction.

Announcements

THE Rev Canon Harold Anson, Master of the Temple, and Prof F R Fraser, director of the Department of Medicine in the British Post Graduate Medical School, have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

AT the annual general meeting of the Chemical Society held on March 28, the following officers were elected *President*, Dr N V Sidgwick , *Vice-Presidents, who have filled the office of President*, Prof G T Morgan and Prof. J F Thorpe ; *Ordinary Members of Council (Town)*, Prof J W. Cook, Prof G. I Finch and Dr J J. Fox , *(Country)*, Mr. W. A. S. Calder, Prof T P Hilditch, Dr F G Mann, and Prof. J. Read

Mr H. L BROOK arrived at Lympne on March 31, on his return flight from Australia in the Miles Falcon cabin aeroplane which he had entered for the Melbourne air race, 7 days 19 hours 50 min. after leaving Darwin. Thus he has set up a new record for a solo flight, being 1 day 2 hours 35 min. better than the record established by Mr J. A. Mollison in 1931, and 13 hours 10 min. better than the unofficial solo 'record' set up by Mr C. J. Melrose in 1934. The aeroplane was a low-wing monoplane with a Gipsy Major (130 horse-power) engine.

A CONFERENCE to discuss current theories as to the cause of swarming of bees and the practical means of controlling it, is to be held on Saturday, April 27, at the Rothamsted Experimental Station, Harpenden, Herts. During the morning the laboratories of the Experimental Station will be open for inspection ; it will also be possible to visit the apiary and to see the work which is being done by Dr Tarr under the Foul Brood Research Scheme Those wishing to attend should notify the Secretary of the Experimental Station not later than Wednesday, April 24

THE next congress of the International Vegetarian Union will be held in Zurich in the middle of July, when papers on eugenics and eubiotics will be read Further information can be obtained from M Henri Hotz, 7 Orenstrasse, Zurich

THE executive committee of the German Society of Men of Science and Physicians has decided to hold its ninety-fourth annual congress on May 24, 1936, as the meeting cannot be held this year The president will be Prof Sauerbruch, with Profs Grote and Zaunich as local presidents.

A CONGRESS of the history of Greek medicine will be held at Athens on May 8–11. It will consist of three sections dealing respectively with scientific work, hygienic organisation and professional matters. Further information can be obtained from the professor of the history of medicine, Prof Dr Kounis, Ecole de médecine, Athens.

DURING its eleventh year, the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation has made twenty-seven grants, fourteen of these being to scientific workers outside the United States Further grants will be made during 1935–36 At present, work will be favoured which is directed towards the solution of problems in medicine and surgery. Application must be made before May 1 Further information can be obtained from Dr. Joseph C Aub, Collis P Huntington Memorial Hospital, 695 Huntington Avenue, Boston, Mass

THE Council of the Royal Statistical Society offers the Frances Wood Memorial Prize, value £30, for competition in 1935 The Prize is offered for the best investigation, on statistical lines, of any problem affecting the economic or social conditions of the people Theses submitted or intended to be submitted as university exercises, and also published papers, are admissible. Essays, which must be either printed or typed, and accompanied by copies of all statistical tabulations, must be sent to the Honorary Secretaries of the Royal Statistical Society, 9 Adelphi Terrace, W C 2, not later than October 31, 1935

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—A civilian educational officer in the Royal Air Force Educational Service—The Secretary (A E.), Air Ministry, Adastral House, Kingsway, London, W.C 2 (April 17). A principal lecturer and master of method in science at the Glasgow Training Centre—The Executive Officer, 140 Princes Street, Edinburgh, 2 (April 18). A principal of the Midland Agricultural College, Sutton Bonington, Loughborough—The chairman of the Governors, County Education Office, St. Mary's Gate, Derby (April 29). An engineer and surveyor of the City of Westminster—The Town Clerk, City Hall, Westminster (May 18).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

Masses of some Light Atoms determined by a New Method

IT has long been realised that the only really certain method of comparing masses by observations on mass spectra is by resolving and measuring naturally occurring doublets which represent small residual differences between the atoms and molecules concerned The recent discovery of deuterium has enabled this method to be applied generally to the lighter elements, and for some time past I have been constructing parts of a new mass spectrograph designed for this work One of these, a new collimator with variable slits, has been tested on the instrument now in use, with results of great interest

The first test object used in the experiments was the easily formed doublet O,CH_4 Under the improved conditions, this was widely and perfectly resolved, and when measured corresponded to a difference of mass as stated below. This result was very disturbing, as the much lower original estimate 0·0350 had been confidently used as a check on the value for H. On examination, it seems now fairly clear that the underestimate was due to imperfect resolution.

The fineness of the lines warranted an attempt on the doublet D,H_2, expected to be about half the width Pure deuterium was introduced and the discharge manipulated in the hope of getting that equal intensity of the lines so necessary in this work. In a number of cases this object was attained and Fig. 1 shows a photometer graph of one of the exceedingly fine doublets photographed

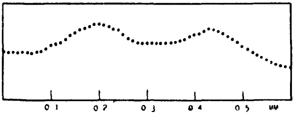

FIG. 1

The apparent separation was estimated as below. The real separation will be probably higher, for the resolution is not yet perfect, but it seems impossible for it to be high enough to correspond to the difference 0·00187 expected from Bainbridge's determinations[1] of H and D each against the same atom He. It seems probable that the bulk of this discrepancy is to be ascribed to the ratio H,He, in which the lines were very unequal in intensity, rather than to that of D,He, in which the conditions were exceptionally favourable. To test that conclusion, I have made a provisional estimate of the wide doublet He,D_2, which within my experimental error agrees with that found by Bainbridge. That his and my estimates of the He,H ratio should have agreed so exactly seems to have been fortuitous

The remaining link in the chain from H to O is the doublet C^{++},D_3 I have succeeded in photographing this, but only with lines of very different intensity and, like the He,D_2 doublet, it is too wide for really satisfactory treatment on my present apparatus The results appear in the following table of doublets, giving the proportional differences in parts per 10,000 and the differences of mass on the atomic scale between the lighter and heavier components

Doublet	Difference of Packing Fraction	Difference of Mass
D,H_2	7·1	0·00142
He,D_2	63·5	0·02550
C^{++},D_3	69·7	0·04195
O,CH_4	23·3	0·0374

I propose to measure all these doublets again with the proper refinements when my apparatus of higher dispersion is completed In the meantime, the following values may be deduced for the masses relative to O^{16}

$$H = 1·0081$$
$$D = 2·0148$$
$$He = 4·0041$$
$$C = 12·0048$$

These must be regarded as provisional, and in no case is an accuracy greater than 1 in 10,000 claimed They are considerably higher than my earlier ones and in better accord with the much more delicate but less direct calculations made from the energy relations in the equations of artificial disintegrations. At the meeting of the Royal Society on March 14 attention was directed by Dr M L Oliphant to the discrepancies on the mass scale revealed by experiments of this kind and a provisional scale of values suggested.

I should like to give a word of warning to those using atomic masses determined by mass spectra These figures may depend on a chain of relationships, and it is often found that the errors here have markedly cumulative effects. It will be well always to examine the complete data from which a single result has been derived The results described in this letter are a good example of the dangers in this work In conclusion, I may say that I am never likely to regret my underestimate of the mass of H made nine years ago, however serious it may ultimately turn out to be, since it played so fundamental a part in encouraging the search for deuterium

New Ion Sources for Mass Spectroscopy

FOR use in connexion with a new mass-spectrograph, I have recently developed a new type of ion source in which positively charged atoms are formed by sparks between solid electrodes in a high vacuum. Spectroscopic studies in recent years have shown that these vacuum sparks are efficient sources of multiply charged ions. Several forms of sparks were tried, the '*trembleur à vide*', the 'hot-sparks' from a large condenser discharge, and finally a spark coupled inductively to a high-frequency oscillating spark circuit. This latter has proved very successful, and an abundance of ions has been obtained, thus far from the following elements: platinum, gold, tungsten, tin, copper, nickel, iron, aluminium, carbon, beryllium and lithium.

The ions were analysed provisionally by the Thomson parabola method after being accelerated by about 20,000 volts. The presence of multiply charged ions is in most cases very striking; spots occur with fractional electrostatic deflections, indicating ions that changed their charge before reaching the electric and magnetic fields. With platinum, for example, ions with all charges up to five occur, and with gold all charges up to four. It is of interest that ions of gold and platinum, which have not been found with other methods, are very easily obtained with these sparks.

Interferometer Measurements of the Red Auroral Line 6300

WE know that considerable interest is attached to certain auroral lines in the region 6300–6400 A. Thus the enhancement of one or more of these lines is responsible for a particular type of red-coloured auroræ[1,2] and, according to the interpretation of the strong green line by McLennan and his collaborators, the OI triplet ($^1D_2 - {}^3P_{0,1,2}$) should appear in this region.

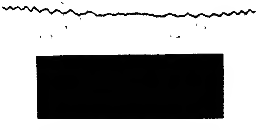

FIG. 1. Interferometer photograph of the red line 6300 and corresponding photometer curve above.

Previous auroral spectrograms taken with instruments of fairly high dispersion have shown two lines, which within the limit of error coincide with the two strongest components of the OI-triplet[3,4], and a faint line has been observed which might be identified with the weakest line of the OI-triplet.

The mean of our present measurements gives $\lambda = 6300·9$ ($\pm$ 1) for the strongest line ($^1D_2 - {}^3P_2$) and $\lambda = 6365·3$ ($\pm$ 2) for the weaker one, which might correspond to ($^1D_2 - {}^3P_1$)[3,4]. Spectrograms in the red[4,5] indicate that bands belonging to the first positive group appear in the region of the OI-triplet.

Some years ago investigations were commenced at the Tromsö Observatory with the object of using interferometer methods for accurate wave-length determinations within the auroral spectrum. Our results relating to the strong green line were dealt with in a recent publication[6], and we are here going to give a preliminary, brief account of some results which refer to the strongest red line 6300.

Just as in the case of the green line we take advantage of the predominance of this red line, so we can use an interferometer without spectrograph, simply consisting of a Fabry-Pérot quartz plate in front of a camera lens combined with suitable filters and photographic plates. Under these conditions only atomic lines and not the fairly strong bands of the first positive group of N_2 can give interference fringes.

During an auroral display (January 15, 1934) an interferometer picture of the strong red line was obtained at the Tromsö Observatory with a 2·5 mm. étalon. The microphotometer curve reproduced in Fig. 1 corresponding to a line through the centre shows that the fringe system is weak, but sufficiently distinct to be measured.

On the same plate were taken two interference pictures of the neon line ($\lambda_{vac} = 5854·110$ A.) in the way and for the purpose described in our previous paper[6]. Comparing the diameters of the rings of the interference picture produced by the aurora with those produced by the Ne line 5854·110, we may decide that the interference pattern produced by the auroræ must be due to a fairly sharp atomic line situated near 6300 A., and only the strongest red line 6300·9 A. measured on our spectrograms can come into consideration.

The possible error of our spectrographic measurements of the red line, being about $\pm$ 1 A., interference pictures with one (2·5 mm.) étalon does not permit us to make an unambiguous determination of the order number n of the rings on the interference pattern. In the interval of uncertainty there are six order numbers which are possible, giving the following values for the wave length:

Interference order = n + 0·536

n = 12500 +	λ = 6300 +
− 2	+ 1·859
− 1	+ 1·347
0	+ 0·835
1	+ 0·322
+ 2	− 0·190
+ 3	− 0·702

One of our values, $\lambda = 6300·322$, is nearly equal to that (6300·328) derived from the electronic OI states given by Hopfield[7]. From direct measurements of the red line with a glass spectrograph (dispersion 29 A./mm.) Hopfield finds the wave-length 6300·23. As the determination of the electronic levels is based on spectra taken with a dispersion of 1·7 A./mm., the wave-length derived from these levels should be most accurate, and this wave-length is, within the limit of error, equal to one of our values for the wave-length of the red auroral line.

In order to fix exactly the true wave-length, we intend to take more interference pictures with étalons of different thickness Further, by continued observations, we hope to diminish the possible error of our spectrographic measurements

Isotope Effect in Band Spectra of Hydrides and Deutrides

THE comparison between the band spectra of hydrides and deutrides has shown, as is well known, that the ratio ρ^2 of the reduced masses, for example

$$\rho^2 = \frac{\mu_{AgH}}{\mu_{AgD}}$$

(where $\mu_{AgH} = Mm_H/(M + m_H)$, $\mu_{AgD} = Mm_D/(M + m_D)$, m_H = mass of the proton, m_D = that of the deuton), calculated in this way, does not agree with the ratio ρ^2 as deduced from the atomic weights As a possible explanation, E Hulthén and W Holst[1] have suggested that the electronic system takes part in the rotation and vibration of the molecule and gives a contribution to the effective moment of inertia

A theoretical discussion may perhaps be interesting If the hydride (deutride) contains an atom with high atomic number, we can assume the distribution of electrons to be spherically symmetrical and start from the distribution of the corresponding negative ion A suitable expression for the electronic density is that given by H Jensen[2]

$$D = \frac{N}{4\pi P_0 r_0^3} \cdot \frac{e^{-X}}{X^3}(1 + cX)^2; \quad X = \sqrt{\frac{r}{r_0}}, \quad r_0 = \frac{a_H}{Z^{\frac{1}{3}}\lambda},$$

Z = atomic number, N = number of electrons, $a_H = h^2/4\pi^2 m_e e^2$, where m_e = mass of the electron P_0 is to be determined by $\int_0^\infty D 4\pi r^2 dr = N$, λ and c are constants corresponding to $1/\lambda$ and c in the table of Jensen[2], and to μ and k in the table of Nagy[3] Calculating the moment of inertia, we get .

$$I_e = m_e a_H^2 \times Z^{\frac{1}{3}} \times 7{\cdot}96 \times f\left(\frac{N-Z}{Z}\right)$$

where $f\left(\frac{N-Z}{Z}\right)$, depending on λ and c, is a function of $\left(\frac{N-Z}{Z}\right)$ only If $\left|\frac{N-Z}{Z}\right| < \frac{1}{10}$, which is certain in our case, we can write :

$$f\left(\frac{N-Z}{Z}\right) = 1 + 3\ 84\left(\frac{N-Z}{Z}\right) + 9\ 4\left(\frac{N-Z}{Z}\right)^2$$

An opportunity for comparison with experimental results is given by the careful investigations[4] of E Hulthén and E. Knave on silver hydride and silver deutride In this case the total angular momentum of the electrons is 0, and the corrections of Kronig and Van Vleck, being proportional to its square, also equal 0 So we obtain a lower and an upper limit for the ratio ρ^2, taken from the rotational structure of the band spectra AgH and AgD, ρ^2 min $= \frac{\mu_{AgH}}{\mu_{AgD}} = 0\ 50497$, and ρ^2 max $= \frac{\mu_{AgH} + I_e/a^2}{\mu_{AgD} + I_e/a^2} = 0\ 50545$ (a = nuclear distance) ρ^2 max is obtained if all the electrons take part in the rotation

E Hulthén and Knave have found $\rho^2 = 0\ 50527$ from the B-values Thus the correction is 60 per cent of the theoretical maximum Using the electronic density D mentioned above, the calculation shows that this correction will be obtained, provided the four outermost electrons take part in the rotation This is the same as saying that the electrons outside a sphere with radius 1 7 a_H are constrained by the hydrogen nucleus to take part in the rotation

We may verify the reliability of the expression D for the electronic density by calculating the nuclear distance of AgH to the first approximation Starting from the charge distribution D of the negative silver ion, we determine the distance from the Ag nucleus at which a positive particle can be in equilibrium The result, 2 78 a_H, is in good agreement with the experimental value[5] 3 05 a_H and indicates that the moment of inertia will be somewhat greater than our I_e, if the effect of the hydrogen nucleus on the electronic distribution is taken into account

I am obliged to Prof E Hulthén, who directed my attention to this question, and to Prof O Klein, for interesting discussions on the subject

Internal Recombination during Photo-dissociation of Polyatomic Molecules

IT has been generally admitted that, in the primary decomposition of a molecule by absorption of light, free atoms or unsaturated radicals are produced In an extensive investigation upon the photo decomposition of carbonyl compounds, Dr R G W. Norrish and his co-workers[1] have advanced the view that an aldehyde molecule can be disrupted into a saturated hydrocarbon and a carbon monoxide molecule in one process This is equivalent to a recombination of the liberated hydrogen atom and alkyl radical at the moment they leave the remainder of the molecule.

The possibility of such a process can be tested directly if the magnitude of the absorbed quantum is large enough to produce excited atoms, or radicals which will recombine to form an *excited* molecule emitting its characteristic spectrum By observing this emission under conditions which prevent the possibility of secondary processes, that is, at very low gas pressures, we should get definite proof of the existence of such an internal recombination

An investigation in this direction has been under taken in this laboratory Polyatomic molecules containing halogen atoms instead of alkyl radicals,

or hydrogen atoms, are better suited for the purpose because the excited halogen molecule liberated during the photo-dissociation process can be easily detected by its emission spectrum, which lies in the visible region. We tried several molecules of the composition $XHal_4$, and $XHal_2$, where X is C or Sn and Hal is a halogen After some unsuccessful attempts, we obtained in SnI_4 vapour under the action of wave-lengths in the range 2500–2150 A a bright visible emission of the spectrum of I_2 with an abnormal distribution of intensity in the bands A detailed investigation confirmed the conclusion which immediately followed from this fact, namely, that the iodine molecule was detached from the SnI_4 molecule in one primary process As the iodine atoms were originally bound to the central Sn atom by valency forces and did not markedly interact one with another, the whole process is equivalent to a recombination of atoms in the very act of photo dissociation, or to a redistribution of valency bonds The energy balance, the influence of collisions with other molecules and other features of the emission so far studied lead to interesting conclusions about the mechanism of the disruption The most important peculiarity is a marked temperature coefficient which indicates the necessity for an energy of activation for this type of photo dissociation

In this connexion we have re-investigated the yellow fluorescence in BiI_3 vapour, observed in this laboratory some years ago[2] Although the spectrum of this fluorescence on closer examination did not reveal any band structure, nevertheless the exact coincidence of its position with that of the iodine spectrum cannot be fortuitous We assume therefore that the mechanism of this emission is the same as that given above, namely, that under the action of suitable quanta and with some thermal activation, an iodine molecule is detached from BiI_3 The continuous or blurred aspect presented by the spectrum emitted in this case may be due to the disturbing influence of the polar BiI radical remaining in close proximity to the iodine molecule which is emitting radiation.

Spectroscopic Constants of the Di-Atom PN

IN a recent paper[1], I ventured to predict that (*a*) "the internuclear distance of PN may be taken as closely approximating to the mean of the experimental values for NN and PP" (p. 28), and that (*b*) "it may be expected that experiment may show that PN has the highest bond constant and mean restoring force in the LK and KL periods" (p. 36).

At the time the paper was written, I was unaware of the experimental work on PN of Curry, Herzberg and Herzberg[2], but the results appear to justify both the above statements.

(*a*) r_e (calc.)[1] $= 1{\cdot}48_7$; r_e (obs) $= 1{\cdot}4869$ A.

(*b*) ω_e (expt.) $= 1337{\cdot}24$ cm.$^{-1}$, whence the bond constant $k_e = 101{\cdot}0 \times 10^4$ dyne cm.$^{-1}$ and mean restoring force $K = 3{\cdot}642 \times 10^{-4}$ dyne are derived. These are without doubt maximum values for the LK and KL periods.

The experimental data are consistent with the observed flattening of the periodicity curves with increasing period numbers The presence of maxima and minima of spectroscopic constants in the symmetrical sub-group of the tenth molecular group is not without interest in connexion with problems of polarity and bonding strength of di-atoms

A Mycetozoan Parasite of *Zostera marina**

IN a previous note in NATURE[1] we pointed out the association of a *Labyrinthula*-like organism with the wasting disease of the eelgrass along the American Atlantic coast Since the publication of this announcement, we have performed a number of experiments in the laboratory and in the natural beds themselves, which indicate that this organism is a true parasite of *Zostera marina*. Communications from other investigators and examinations of specimens submitted from various points show also that this parasite is uniformly present in the infected beds on the Atlantic coasts of both Europe and America

The parasitic habit was first demonstrated in modifications of Cienkowski's moist chambers[2]. In those the actual migration of the spindle-shaped cells from fragments of diseased leaf and the invasion of healthy leaf tissue could be clearly followed. Consistent infection occurred in thirty slides, usually within eight to forty-eight hours. In only one case did a filamentous fungus make its appearance—a contaminated check preparation.

Field experiments were conducted in several beds near Woods Hole, Massachusetts Slips of diseased and normal leaf were fastened in alternate order to healthy green leaves Local darkening and characteristic streaking of the 'inoculated' leaves to form the pattern anticipated by this arrangement followed within one or two days The experiment was repeated four times during the later part of the summer and corresponding tests were made in aquaria with the same results. Sections prepared from the newly infected areas showed heavy infestations of viable *Labyrinthulæ* Such sections attached to clean plants brought about infection of the new host.

We were unable to grow the organism on artificial media or to maintain it long without its host in filtered sea water , but from microscopic observations and from field experiments it is evident that the *Labyrinthula* is capable of attacking and destroying healthy leaf tissue independently of other organisms The rapidity with which it produces infection indicates its extremely aggressive habit. Thus far it has not been identified with any of the described *Labyrinthulæ*.

It seems well established that the *Ophiobolus* isolated from diseased eel-grass by Dr. Petersen[3], Miss Mounce[4] and by Dr. Tutin[5] varies in abundance and activity over the affected areas. The mycelium of the fungus occurs in the Woods Hole region, but in extremely minor quantities—it is far from universally associated with the disease. We have not

* Contribution No 87, Woods Hole Oceanographic Institution and Journal Series Paper of the N.J Agr. Exp Station.

been able to find the pycnidia of this form upon any of the specimens from the coast of Maine, south, though they are very abundant upon the fruiting stems of plants sent us by Miss Mounce from St Andrews, and have been described by Dr Petersen as very profuse in the Danish beds

We could not discover the *Labyrinthula* in the longer, wider-leaf *Zostera marina, L*, from Nanaimo, Departure Bay, B C, on the Pacific coast, though this grass was spotted and infested with a variety of other parasites Despite their activities, the grass at Nanaimo was unusually abundant last year

Wasting Disease of *Zostera marina*

THE variation in the width of the leaf of *Zostera marina* cannot be put down to any one particular cause In common with all water plants, the size of the leaf is probably a reflexion of the nutritional balance in the plant itself, as is shown to be the case by Pearsall and Hanby[1] for certain *Potamogeton* species

Many of the circumstances enumerated by Dr Cottam[2], such as reduced salinity, abnormal temperatures, short period of submergence, low light intensity, etc, by altering the nutritional balance, doubtless react to produce narrow-leaved plants

That the production of the narrow leaved plant is not a simple reaction is suggested by the fact that, in some places on the English coast, plants with leaves of all sizes grow mixed up together, while at other places, only *Zostera marina* var *angustifolia* can be found, though the large-leaved type was abundant in 1921 Nor is the size of leaf a matter of age alone, for these narrow-leaved forms flower just as profusely as the broad-leaved plants

All this goes to suggest that, in the disappearance of *Zostera*, one has to deal with a large number of circumstances and not with a single catastrophic event

Fibre Saturation Point of Wood

THE fibre saturation point of wood (f s.p), which is the minimum moisture content in equilibrium with a saturated atmosphere, is commonly estimated indirectly from the point at which (*a*) shrinkage begins, or (*b*) a sudden increase occurs in the compressive strength[1,2], on lowering the moisture content from the green state. Though these methods agree fairly well in defining the f s.p of Sitka spruce as about 25 per cent moisture content[3] (basecrsity Field[5] weight of the wood), it is found that many factors, show measurable shrinkage at much higher moisture contents than those indicated by method (*b*)

Other research[4] at this Laboratory, which required the vapour pressure isothermal of Sitka spruce flour above 95 per cent relative humidity, showed that, on adsorption, moisture contents of about 35 40 per cent were attained before saturation was reached, which considerably exceeds the figure quoted above

Desorption, on the other hand, showed a measurable drop of about 0 4 per cent in relative humidity on a slight drying from moisture contents as high as 90 per cent, the effect probably persisting up to even higher values Others[5] have noticed that the loop does not close at the adsorption saturation value, but have not investigated higher moisture contents Thus there is no well defined f s p , and there may well be a large moisture content hysteresis at the saturation value itself, which suggests that the shrinkages observed at high moisture contents are associated with the drop in vapour pressure found on the desorption curve

The discrepancy between the f s p obtained from method (*b*) and that from the adsorption isothermal may be accounted for by the compression which, opposing the swelling presure of the wood, raises its vapour pressure[6], thus bringing to saturation a sample of 25 per cent moisture content that was initially unsaturated In support of this view, samples of Sitka spruce of higher strength in compression are found to show a lower apparent fibre saturation point[3]

Plotting the observed shrinkage against swelling pressure calculated from the desorption curve shows a decreasing strain stress ratio on drying, corresponding to the decrease of compressibility of wood which is already well known below 25 per cent moisture content

The Smell Emitted by Seaweeds

THE offensive odour given off from masses of rotting seaweed which occasionally accumulate on the shore is a not unfamiliar phenomenon of the sea side There can be little doubt that an important constituent of the smell is sulphuretted hydrogen produced perhaps in part by the putrefactive reduction of the ethereal sulphates which form so marked a feature of many marine algæ

Belonging to a somewhat different category is the particularly unpleasant smell reminiscent of phosphorus given off on drying certain members of the genus *Polysiphonia* I have recently been able to identify methyl sulphide as the odoriferous principle in this case The origin of this substance is less easy to account for and investigations directed towards the elucidation of this question are in progress Preliminary experiments would suggest that methyl sulphide is a product of modified vital activity rather

than a post-mortem decomposition product, in as much as it begins to be evolved very shortly after the seaweed has been gathered and is not apparently given off by material which has been dipped in boiling water

The natural occurrences of methyl sulphide are not numerous, and it is worthy of note that one of these is petroleum from Ohio, the finding here recorded is therefore at least not inconsistent with the theory of the algal origin which has been suggested for some oil-fields.

Germination of Resting Fungal Spores

I have read with interest Mr Robert McKay's letter[1] on the germination of oospores of *Peronospora Schleideni* He notes the remarkably persistent oogonial wall, which "forms an additional protective layer" around the oospore, and the still more persistent oospore wall In germinating these highly resistant spores he lays claim to no special method in course of time, in this case of years, the spores germinate when placed in water

During the last ten years, I have spent a considerable amount of time in an attempt to devise a reliable method of obtaining the germination of the similar, though not quite so resistant, oospores of *Phytophthora Cactorum*, in sufficient numbers for cytological study. After trying many and varied 'agents', I finally obtained germination in quantity by exposing three-months old oospores to a temperature of 1°–3° C for a month and then soaking them for one or two weeks in water, kept constantly renewed It appeared later that the spores could be older, and the refrigeration period longer, and still give an equally good result[2].

When comparing my experiments with those of other workers upon the germination of resistant spores, I felt that we had no logical method of approach to the problem It was by trial and error that results were finally obtained in some cases one method, in others another, chanced to be effective At the risk of appearing to state the obvious, I would direct attention to the following facts that suggest a line of attack in such experiments.

(1) That the wall of these resistant spores is, as a rule, at least two-layered · the inner thick and of a reserve substance such as a hemicellulose ; the outer thin and of 'fungus cellulose', and practically impermeable

(2) That the substances composing both wall layers are in a colloidal state

(3) That germination cannot take place until (*a*) the spore has fully matured—a process, not at all understood, which involves a time factor ; (*b*) the wall is rendered sufficiently permeable to admit water and oxygen.

(4) That the various devices tried and claimed as agents initiating germination (namely heat, cold, acids, carbon dioxide, bacteria, etc.) appear to do one of two things, provided they are of a suitable intensity or concentration . (*a*) form small cracks in the wall, (*b*) bring about a change of colloidal state. (Agents such as bacteria may be effective through carbonic acid produced.)

(5) That since the spore, though dormant, is a living thing with carbon dioxide accumulating within it, the change in the nature of the wall will in course of time come from inside, that is, time is a factor in germination as well as in maturation.

Extrusion of Cells in the Tubules of the Epididymis

Mr. P. G. 'Espinasse has remarked[1] that the extrusion of nuclei which has been observed to occur from the epithelium of the oviduct in the mouse could not be closely related, as had been suggested, to the œstrous cycle His conclusion on this point seems to derive indirect support from a comparable phenomenon which takes place in the epididymis of the mouse and rat In those tubules of the epididymis which are lined with a single layer of columnar cells the nuclei of which are close to the basement membrane, a process of cellular extrusion is particularly well seen, though it occurs also in other tubules where the epithelium is cuboidal

Microscopic sections suggest that the actual process could be reconstructed as follows Here and there a nucleus becomes separated from the uniform row of its fellows and advances towards the lumen of the tubule. As it approaches the free surface, it may be preceded by a bulging of the cytoplasm into the lumen Eventually the nucleus, sometimes surrounded by cytoplasm, becomes detached and lies free in the cavity of the tubule This extruded body often appears to be a living cell, showing no pyknosis or other obvious signs of degeneration

Whatever significance may be attached to the phenomenon, it appears to be of frequent occurrence in the healthy epididymis of the adult mouse and rat, and cannot readily be attributed to any periodical cycle connected with the sexual function.

Hydrogen Ion Concentration of the Alimentary Canal in Psychodidæ (Diptera)

Insect physiology, and particularly the physiology of digestion, is more or less intimately correlated with the life-history and other environmental factors. An attempt has therefore been made to find out the correlation, if any, between the hydrogen ion concentration of the alimentary canal and the different feeding habits in the family Psychodidæ, which contains two sub-families, namely, Phlebotominæ and Psychodinæ. The former is easily separable from the latter by its blood-sucking habit.

The entire alimentary canal of four common species belonging to two different genera was dissected in a minimum quantity of bromthymol blue and carefully laid out on a slide. The subsequent reaction

was enhanced by puncturing a few holes in the thicker region of the alimentary canal The changes in colour of the gut in all the four species were carefully noted and their approximate pH value determined by comparison with a Hellige standard colour disc for bromthymol blue The ranges of variation of pH in each species are those of different regions of the gut and to some extent include the individual variations.

The accompanying table shows that the degree of variation in the pH of the alimentary canal is small, yet it is suggestive enough to indicate that the alimentary canal of the blood suckers is slightly more acidic than that of those which do not suck blood The relation of the acidity of the gut with the development of flagellates inside it is being investigated and will be published elsewhere.

	pH value

Simultaneous Travel of a Surge of Stress and a Group of High-Frequency Waves of Stress in a Steel Wire

THAT a high frequency longitudinal vibration will travel more slowly than a low frequency one may be qualitatively foretold from Rayleigh's[1] treatment of the effect of lateral inertia on the natural period of longitudinal vibration of cylindrical rods. However, when Rayleigh's formula is applied to the case given by Dr. Wall[2], where the wave-length is stated to be 18 inches and the diameter 0 123 in, the effect of lateral inertia is found to be negligible

Rayleigh's formula has been experimentally investigated, by R. W. Boyle and myself[3] and by Muzzey[4], and found to be applicable over a range of the ratio of wave-length to diameter including this case. It is suggested that the necessity of postulating a hitherto unknown effect may be avoided by assuming that the group of waves has a higher frequency than that given by Dr Wall, determined possibly by the natural period of a clamp, this high frequency being 'modulated' at the inter-clamp frequency by successive reflections, and 'demodulated' in the amplifier, which the oscillograms show to have the necessary characteristics.

Dr. Wall's oscillograms show that the ratio of the two velocities is about 1 : 1·3 and Poisson's ratio for iron may be taken as 0·3 (Kaye and Laby). These values inserted in Rayleigh's formula give a ratio of diameter to wave-length of 1·2. The results of Boyle and myself show that Rayleigh's formula is *not* applicable when this ratio exceeds 0·55, probably due to the neglect of shear stresses, the approach to resonance of radial vibration, and viscosity Field[5] has given an analysis which includes these factors, and whether or not this analysis can be applied to explain the interesting results given by Dr Wall, it is clear that Dr Wall's method of measuring the velocity of longitudinal vibrations may be adapted to an experimental investigation of the factors included in Field's analysis

Science and Social Progress

MAY I suggest that the decline of the adventurous spirit is due not so much to standardisation and mechanisation, as might be gathered from the leading article in NATURE of February 16, p 245, as to specialisation? A specialist, as I have said elsewhere, is "a human being who has narrowed the sphere of his activity at the expense of his social instincts, thereby becoming but a fraction of a man He sees a field of activity as brightly lit, perhaps, but as limited as the field of a microscope, and not infrequently it is as though the microscope was a little out of focus There is a blurring as of things too close to the eyes to be distinctly seen"

I am under no illusion that specialisation can be dispensed with altogether, but I am heterodox enough to believe that we should be more truly civilised if there were more jacks of all trades and fewer masters of one. How can any man who has only read, let us say, Chapter xx of the 'book of life' hope to acquire that comprehensive vision of the human adventure in time and space, so essential to ensure sane social development?

Since mechanisation has been mentioned, I should like to take this opportunity to combat the belief now being revived in various quarters, that machinery, after all, does not cause unemployment. It will be seen that the subject is not irrelevant This particular fallacy was exposed 116 years ago by Jean Sismondi as follows· "Every new product must in the long run give rise to some fresh consumption But let us desist from our habit of making abstraction of time and place Let us take some account of the obstacles and the friction of the social mechanism And what do we see? The immediate effect of machinery is to throw some of the workers out of employment. A certain kind of equilibrium, it is true, is re-established in the long run, but it is only after a frightful amount of suffering."

In short, it is little consolation to a man thrown out of employment now, to know that 'in the long run' and 'on the average' scientific and technological development creates new opportunities In the long run (as I think Mr. Keynes once remarked) we are all dead Adjustment of the individual to mechanical progress, with less of both short run and long run unemployment, would be easier if men were less specialised, better equipped for turning readily from one type of employment to another

The Oblong or Truncate-tailed Ocean Sunfish, *Ranzania truncata*, at Mauritius

IN studying the history and distribution in the three great oceans of the very rare pointed tailed sunfish *Masturus*, I have had to disentangle it in the literature from the other two genera of the family Molidæ—*Mola*, the round-tailed genus, and *Ranzania*, the truncate form. The former, known since Roman times, is found in the three central oceans, but to my surprise, *Ranzania*, while recorded from the Atlantic and Pacific, has seemingly never been described from the Indian Ocean. However, there is known to me an unpublished figure and description of it in this ocean and it seems well to put these on record.

Nicolas Pike was U.S. Consul at Port Louis, Mauritius, from 1867 until 1874. During these years, he made extensive natural history collections, drawings and studies and brought back to New York in 1874 eight volumes of drawings of fishes, most of them in colour. In 1905, these were purchased by J. Pierpont Morgan and presented to the library of the American Museum of Natural History. Finding these among our treasures, I published in 1929 a sketch of Pike's life and an analysis and description of his 486 paintings[1] of fishes. These I listed alphabetically under the name of the fish. Number 324 is his "*Orthagoriscus truncatus* Retz., molle, poisson lune". The figure is noted as made from a stuffed specimen in the little museum at Port Louis, June 25, 1873, and is found on pl. 8 of vol. 6.

This figure is somewhat crude but plainly that of *Ranzania truncata* in its oblong form, truncate tail, in the relative positions and conjunction of dorsal, caudal and anal fins, in the presence of bars on the lower side of the head as far back as the pectoral fin, and in the imperfect markings on the hinder part of the side with some few on the dorsum. Here is Pike's brief and untechnical description.

SUNFISH—CREOLE MOLLE

Height of body less the half total length. Skin very smooth, divided on back into small hexagonal scutella [drawing of one with dots]—only the raised dots visible elsewhere. It appears to have been marked nearly all over with lines, blots and dots but so effaced I can only trace what are shown in sketch. I think the broad stripe on bare part in front of D was yellow, also stripes between lines, but where I have put large round spots, they were either white or yellow with a dark center. The entire color is a grey brown now. Snout round—a dark boss of some kind above snout, a deep hollow for P behind them—2 have scutes in front.

Numbers [of fin rays] about D' 15 or 16—A 15 or 16—C 23 or 4, P 12. Above boss on head is a rise and beyond a depression (rough sketch) along back at top.

This figure and description made sixty-two years ago constitute the first and only record known to me of the presence of the oblong sunfish in the Indian Ocean. Thinking that Barnard might have a record of it for South Africa, I consulted his "Monograph"[2]. In this he lists three specimens in the South African Museum, from False Bay, Table Bay and Dassen Island—all to the west of Cape Agulhas, through which runs the meridian dividing the Indian and Atlantic Oceans.

Ranzania is an inhabitant of warm seas, and this is very far south for it. The average latitude for the three localities is about 34° S. and the mean annual temperature is about 60° F. This is cold water for this sunfish and hence one may judge that *Ranzania* is not endemic in Cape waters. Add to this the fact that it is an exceedingly poor swimmer and hence could scarcely have reached South Africa by its own locomotive powers, then how did it come to these parts?

The answer is to be found in the currents in the western Indian Ocean. *Ranzania* is found at Mauritius, in the path of the Southwest Drift of the Equatorial Current of this ocean. In about lat. 30° S., this drift unites with the Mozambique Current to form the Agulhas Current, which sweeps around the Cape of that name, and turns north-westward around the Cape of Good Hope.

In my judgment, *Ranzania* was brought from Mauritius or elsewhere in the western Indian Ocean by these currents to South Africa, and, since False and Table Bays act as natural traps for the back-wash of the current as it sweeps west and north-west, these specimens were thus stranded. These three captures of *Ranzania* in South Africa are to me so many additional proofs of its occurrence in the western Indian Ocean.

Diffusion of Hydrogen through Aluminium

THE solubility of hydrogen in aluminium has been determined by Sieverts[1], Röntgen and Braun[2], and Röntgen and Möller[3]. These authors agree that the gas is completely insoluble in the solid metal at all temperatures below the freezing point. There are certain difficulties in the direct determination in this case, and we have therefore attempted to detect the diffusion of hydrogen through the solid metal. The method used is that described in a recent paper[4].

We find that hydrogen diffuses through aluminium at a rate which is easily measurable above 400° C. Preliminary measurements show that it follows the usual diffusion law with regard to the effects of temperature and pressure, namely,

$$D = k\sqrt{P}\, e^{-b/T},$$

b having a value of about 14,000. The rate of diffusion at 400°–600° C. is of the same order as that of hydrogen through copper, but the temperature coefficient is much larger. We hope later to publish exact data.

The fact that hydrogen can diffuse through solid aluminium shows that it must be soluble, but does not indicate the degree of solubility.

Atmosphere of the Planet Mercury

I NOTICE, in the Supplement to NATURE of February 9, that the existence of an atmosphere on the planet Mercury has again been pronounced impossible on account of the small mass of the planet.

As a systematic observer of Mercury, with a powerful telescope, in 1927, 1928 and 1929, I wish to state, in full accordance with Schiaparelli, that the dusky spots of the planet are frequently faded, while some of them are sometimes even totally extinguished, by local clouds. These may be due to dust, and appear white, or even brilliant, on the limb, stretching there occasionally over three thousand miles in length, and it is thus obvious that such phenomena establish beyond doubt the existence of the highly rarefied atmosphere of Mercury, which is invisible, like that of Mars.

E. M. ANTONIADI

Paris,
Feb. 27.

Points from Foregoing Letters

FOLLOWING upon an improvement in his apparatus, Dr. F. W. Aston finds higher values for the masses of hydrogen, deuterium, helium and carbon atoms; the new values are in better accord with those deduced from energy changes during the artificial disintegration of those elements. The new determinations were made by comparing with the mass-spectrograph, to which a new collimator with variable slits was added, the masses of doublets (that is, atoms and groups of atoms having nearly the same mass/charge ratio).

Prof. A. J. Dempster describes a new way of obtaining positively charged ions of the metallic elements, including gold and platinum, for use with the mass spectrograph. He employs a spark coupled inductively to a high-frequency oscillating spark circuit, and obtains many ions with multiple charges.

The red colour of certain auroræ may be due to electrically excited oxygen, which emits a 'triplet' of wave-lengths in the red region of the spectrum. Mr. L. Harang and Prof. L. Vegard have determined more accurately the wave-length of the strongest component of the triplet by means of an interferometer, and find that it agrees with the wave-length observed by Hopfield in the case of oxygen in the OI state.

From spectroscopic analysis of light obtained with silver compounds of hydrogen (H) and heavy hydrogen (D), the ratio of the (reduced) masses of H and D atoms has been deduced; it does not agree with the ratio deduced from their atomic weights. Mr. L. Hulthén calculates that this discrepancy would be accounted for if the four outermost electrons of the silver atom took part in the rotation of the nucleus, which rotation is assumed to be responsible for the band spectrum.

Prof. A. Terenin states that when SnI_4 vapour is decomposed by ultra-violet light, visible light is emitted corresponding to that characteristic of iodine molecules. This he considers shows that, under the influence of light quanta, not only are the bonds of the original molecule broken, but also an instant recombination between the liberated radicles or atoms can take place. Prof. Terenin accounts in this way for the yellow fluorescence of bismuth tri-iodide which falls in the same region as the iodine spectrum.

Mr. C. H. Douglas Clark directs attention to the fact that the value for the inter-nuclear distance between phosphorous and nitrogen, and also other molecular constants, as calculated by Curry, Herzberg and Herzberg from observations on the spectrum on the PN molecule (phosphorus vapour electrically excited in nitrogen gas) agrees with certain qualitative predictions which he recently made, unaware of their experimental work.

Evidence that a slime-mould (similar to *Labyrinthula*) is responsible for the wasting disease of the eel grass, *Zostera marina*, along the Mediterranean Atlantic coast, is adduced by Mr. C. E. Wren. A fungus, *Ophiobolus*, has also been suggested as the causative agent, but Mr. Wren finds that it is not always associated with the disease.

Dr. R. W. Butcher believes that the narrow-leaved variety of *Zostera*, which is more resistant to the wasting disease, is produced by a change in 'nutritional balance', and that the disappearance of the wide-leaved variety is due to a variety of circumstances.

Mr. W. W. Barkas finds that the moisture content of sprucewood flour (Sitka or tide land variety) in equilibrium with saturated air, that is, its fibre saturation point (f.s.p.), is greater when the wood is being dried from a moist state (desorption) than when it is absorbing moisture from the air (adsorption). The f.s.p. is also frequently deduced indirectly from the percentage moisture when (1) shrinkage occurs, or (2) sudden increase in compression strength occurs, but in the case of many woods the values obtained by these two methods do not agree. Mr. Barkas suggests that the compression which, opposing the swelling pressure of the wood, raises its vapour pressure also causes a decrease in the water content needed for saturation and accounts for the divergence in the f.s.p. deduced by methods 1 and 2.

The unpleasant smell given off on drying by certain red sea weeds (genus *Polysiphonia*) is due to methyl sulphide, according to Dr. P. Haas. He points out that methyl sulphide is also found in petroleum from Ohio, a fact which supports to some extent the sea-weed theory of the origin of petroleum.

Mr. S. Mukerji finds that the blood-sucking minute moth flies (*Phlebotomus*) have their alimentary canal somewhat more acid (lower pH) than the non-blood-sucking species. The blood-sucking *Phlebotomus papatasii* is a carrier of *Leishmania tropica*, a protozoon which causes the malaria-like fever kala-azar in India.

Mr. D. O. Sproule points out that, according to Rayleigh's formula, high-frequency vibrations travel more slowly than low-frequency ones, but the difference in their speed in a steel wire, recently reported by Dr. Wall, is too great to be explained in that way, unless the frequency of the group of waves was rendered greater by the natural period of one of the clamps used. Mr. Sproule points out that Dr. Wall's method of measuring the velocity of longitudinal vibrations would be useful in investigating shear stresses, viscosity and radial vibration.

Research Items

Pollen Analysis from the Norfolk Fens. An attempt to reconstruct the conditions of discovery of a bronze spear head with loops at the junction of socket and wings of the Middle Bronze Age has recently been described by H and M E Godwin, J G D Clark and M H Clifford (*Proc Prehist Soc East Anglia*, **7**, pt 3) The discovery was made some years ago at Queen's Ground, Methwold Fen, by Mr John Harrod, of Methwold, from whom it was obtained for the University Museum of Archæology and Ethnology, Cambridge The site was visited by members of the Fenland Research Committee, to whom Mr Harrod was able to indicate the horizon of discovery very closely The spear-head was found at the base of the lowest draw of peat The level indicated by attendant circumstances was confirmed by recognition of a well-marked horizon of the surface of the undisturbed peat in the disused trench Uncontaminated samples of peat were taken, the peat in each instance overlying chalky boulder clay As the result of the pollen analysis, bore *A* appears to have included three major phases (*a*) an early phase with high birch and pine pollen values, (*b*) the middle phase with overwhelming dominance of alder pollen, and (*c*) the latest, with co dominance of ash and alder pollen and showing in its last stages small amounts of beech pollen and high values for hazel pollen The earliest phase certainly represents the end of the Boreal climatic period and the base of (*b*) the early Atlantic This is supported not only by the change over from pine and birch to alder, but also by the presence in small amounts of oak, elm and lime, with the two latter genera at first dominant over the oak Probably the change from (*b*) to (*c*) indicates a change to generally drier soil conditions with an extension of the fen area locally covered by fen carr (scrub) or fen woods The record of beech pollen below a late Middle Bronze Age horizon is of interest to botanists since precise evidence is lacking of the history of appearance and spread of this tree in Britain

'Fossil Tradition' in Stone Implements. Under this title, M. A. Vayson de Pradenne contributes to *Antiquity* for March a study of certain anomalies encountered in stone age industries—more particularly in certain industries of North Africa which have frequently been the subject of comment and conjecture Excavators have long noticed the occurrence in prehistoric deposits of objects with two distinct patinas Thus in the Mousterian deposits of La Quina, flints shown to belong to the lower deposits by their deep yellow patina have been found in the upper deposits They had been rechipped and used again by the later inhabitants of this site, as is shown by the white patina characteristic of the upper deposits. Certain very peculiar specimens are found in North Africa with rough chipping on one side only accompanied by a tang handle of neolithic type. Since 1919, Reygasse has described numerous artefacts at Bir-el-Ater of which the Mousterian character is supplemented by tanged specimens Further, there is a whole group of various implements which is supplied with handles. This Aterian industry is widely distributed throughout North Africa and is generally found on the surface or at a slight depth in brick-earths the upper portion of which has been re-arranged In the Abri Alain culture, recently described by M Pallary (see NATURE, **134**, 975; 1934), are found in a group of contrasted association certain tanged objects exactly like those of the neighbouring Champ de Tir of Eckmuhl, and it cannot be doubted that the type was borrowed by the inhabitants of the Abri Alain from the old industry nearby, which was as 'fossil' to them as it is to us. Other caves near the Abri Alain, as recorded by M. F. Doumergue, include in their culture patinated flints of a palæolithic facies, also from the Champ de Tir These implements introduced a new type into the industry which took them over, and serve to show that identity of type need not indicate either direct connexion or contemporary influence

South African Fisheries. In Dr Cecil Von Bonde's Report, No 11, of the Fisheries and Marine Biological Survey, Union of South Africa, for the year ending December 1933 (1934), a résumé of operations of the R S *Africana*, and a list of the stations and salinity results occupy the first part, the second part containing investigational reports Of these, the report on savings-trawl investigations in relation to the conservation and regulation of the Agulhas Bank sole fishery by J M Marchand is of much importance The Agulhas Bank mud sole or east coast sole, *Austroglossus pectoralis*, becomes sexually mature and spawns for the first time at an average minimum length-size of 12 in With a size-limit of 12 in. the percentage of undersized and immature soles in the commercial catches procured with the trawl-gear at present in use is too high Investigations were carried out in order to find trawl-gear of such form, construction and mesh dimension as would allow the escape of as high a percentage as possible of soles of less than 12 in in length, at the same time guarding against the escape of too many mature and marketable fish The main result is to show that the use of a larger-meshed saving-panel in the back or upper side of the cod end of the trawl demonstrates an enormous saving of small, immature and non marketable fish, especially soles, but also other species; the percentage escapes of marketable soles is very low It is recommended that a certain defined breeding area be closed to trawling for five years, and that a general and special mesh and dimensional regulations be enforced with respect to trawl-nets, a savings-panel to be inserted in the cod-end.

Feeding Mechanism in *Diastylis*. Mr Ralph Dennell, in describing the feeding mechanism of the cumacean crustacean *Diastylis Bradyi* (*Trans. Roy Soc. Edinburgh*, **58**, Part 1, No. 6; 1934), has carried out his researches both on the living animal and on careful preparations of the mouth parts, which show the features of a typical filtratory malacostracan There is, however, a peculiar median process projecting into the filter chamber which is of great importance in the working of the feeding mechanism and apparently has not been noticed before in the Cumacea The filter current is due to the pumping action of the maxillæ and maxillipeds, made possible by the maxillary valve and median process, and to the action of the epipodites in sucking a subsidiary

current through the filter chamber It is helped to a large extent by the respiratory current The author suggests that the ancestral cumacean probably possessed certain features shown by the primitive *Gnathophausia* and *Lophogaster* He intends to follow up the present investigation with one on the feeding mechanism of *Apseudes*, in the hope that it will be possible to describe the evolution of the *Cumacea* and *Tanaidacea* as functionally derivable from a group of primitive mysids which took to burrowing in mud, as a change of habitat is shown in other cases to have a profound effect on the crustacean feeding mechanism

Hemipterous Insects from Ireland. Mr J N Halbert has recently published a lengthy annotated list of the Irish Hemiptera, especially of the Heteroptera and the Cicadina group of the Homoptera (*Proc Roy Irish Acad*, **42**, (B), No 8, 1935) For the first time information on the insects in question is brought together with the object of providing a comprehensive survey of the distribution of the species occurring in Ireland As might be expected, the Heteroptera, or plant bugs, have been more extensively collected than the Cicadina Out of 455 British species of this suborder, 253 are shown to be found in Ireland This relative paucity of the Irish fauna is regarded as being due more to past geological changes, resulting in isolation, than to such ecological factors as climate and soil Of the Cicadina, and the allied Psyllina, the Irish species number 153, or less than half of those recorded for the British Isles as a whole These two groups, however, have been less intensively collected, their identification is often beset with difficulties and much work remains to be done Their species are merely enumerated without annotations, the list being tentative in character. The paper as a whole extends to more than 100 pages and is provided with a useful bibliography dealing with Irish faunistic records

Epidemiology of Winter Outbreaks of Parasitic Gastritis in Sheep. In the course of an epidemiological inquiry into the severe outbreaks of parasitic gastritis which occurred during the winter months of 1933–34 in the British Isles, Mr. E L. Taylor (*J Comparative Path and Therapeutics*, **47**, pt 4, Dec 1934) found that the epidemic was chiefly associated with heavy infections of species of *Trichostrongylus* *Haemonchus* and *Nematodirus* did not appear to have been involved. Inquiries on the Romney Marsh showed that 43 farmers lost £10,341 during the outbreak Most of these losses, however, took place while the sheep were away from the Marsh for winter grazing The outbreak was associated with a prolonged period of drought. A gradual storage of potential infective material probably took place on the ground during the drought, which may or may not have terminated in a mass development of infective larvæ, depending upon the advent of a period of damp weather of sufficient duration for the infective larvæ to develop Experiments on the effect of diet on the susceptibility of lambs to worms showed that more worms develop in sheep fed on a deficient diet than in those receiving a full ration; and that those on an adequate diet eliminated their worms more readily than those on an inadequate diet After a period of drought the herbage is short, scarce and of very poor quality, leading to maximum intake of infective larvæ, and actual under-nourishment of the sheep. It is advised that, where a shortage of pasture is threatened, the sheep should receive an ample allowance of concentrated food and that use might be made of the application of nitrates to some of the pastures towards the end of the summer, to stimulate the growth of grass of a more nutritious quality

Improved Methods of Vegetative Propagation. An article entitled "Working up Stock" appears in the *Fruit, Flower and Vegetable Trades' Journal* of February 2, 1935 The identity of the author is hidden behind the pseudonym "Crusoe", but the subject-matter reveals a vigorous awakening of the nursery trade to present-day conditions, as relieved by the provision of import duties on foreign produce It is shown that seed propagation of several plants is slow in comparison with the newer methods of vegetative propagation suggested by the article Lupins may be raised as cuttings from the abundant shoots at the base of old stems *Anchusa* may be multiplied by root cuttings, but attention must be paid to polarity the piece of root must be planted in the same position in which it naturally grows Gaillardias and *Gypsophila* may be propagated from pieces of the fine root An interesting improvement relates to the propagation of hyacinth bulbs The central conical stem is scooped away until the bases of the scales are exposed Planting in ordinary soil induces the formation of innumerable small bulbils from the scales, these can then be grown to suitable size It is interesting to note that these methods of vegetative propagation are as prolific as seed propagation, but have the additional advantage that all the vegetative produce from one plant (that is, a clone) is uniform in colour, shape and size—a very important factor in commercial work

Rust Fungi in Scotland. The study of fungi rests, perhaps more than that of any other group of plants, upon traditions of observation and nomenclature established by highly scientific amateurs Scotland had her share of such men Greville really initiated the study in 1823–28 by the publication of the "Scottish Cryptogamic Flora" He was followed by the Rev. M J Berkeley, and in 1879, the Rev John Stevenson published "Mycologia Scotica" Many rust fungi were described by these authors, but Trail's "Revision" of 1890 was the latest authoritative account until 1934 The Edinburgh Botanical Society has recently published a paper on "The Distribution of the Uredineæ in Scotland" by Dr Malcolm Wilson (*Trans Edin. Bot. Soc*, **31**, pt 3, 345–449; 1934) Records are classified into eleven districts, each being a natural division bounded by watersheds. Trail's records have been more than doubled in number in the present publication The account is not merely a list of new records, but also attempts to trace the influence of several factors on distribution Some difficult problems are disclosed *Puccinia vincæ*, for example, occurs in only one station, though *Vinca minor* and *V major*, its hosts, are widely distributed. *P. agrimoniæ* and *P perplexans* have similar local distribution, and attack plants common in all parts. *Phragmidium rubi* and *Puccinia sonchi* occur only near the sea, though their hosts are found abundantly inland Several species occur in Scotland, but not in England, whilst *Puccinia Porteri* and *Uredinopsis filicina* are new British records.

Clay Minerals. In Prof Paper 185G of the United States Geological Survey, C S Ross and P. F Kerr continue the record of their investigation of the clay minerals by chemical, optical, X ray and dehydration methods. In 1931 they described kaolinite, dickite and nacrite, and their present study shows that *halloysite* is a fourth member of the group, related to, but distinct from, kaolinite Previously described as amorphous, halloysite is now known to have a crystal structure The X-ray diffraction pattern has a number of lines in common with that of kaolinite, but in each case there are independent sets of lines Like kaolinite, halloysite appears to be always the result of weathering, whereas dickite and nacrite are characteristically hydrothermal products *Allophane* is a genuinely amorphous material that is commonly associated with halloysite It has no crystal structure and no definite chemical composition The name includes all materials that can be regarded as mutual solutions of silica, alumina and water with only minor amounts of bases

Recent Developments in Molecular Rays. I V Guillemin has discussed recent work—since 1931—on molecular rays (*J Franklin Inst*, Jan. 1935) The scattering of molecular beams by gases has been calculated on quantum theory and also measured experimentally, with satisfactory agreement The diffraction of molecular beams on crystal surfaces has been observed—this phenomenon is often obscured by adsorption and re-evaporation after a finite time Magnetic and electric dipole moments have been measured for a number of atoms and molecules, including the hydrogen atom measured by Rabi under conditions such that the proton moment may be determined Experiments have been devised to examine the re-orientation of atoms oriented by magnetic field when passed through a second field at an angle to the first A number of other applications of the method are described, and a number of references are given.

Crystal Oscillators for Radio Transmitters At a meeting of the Wireless Section of the Institution of Electrical Engineers on March 6, a paper was read by Messrs. C F Booth and E J C Dixon on the application of the piezo-electric crystal oscillator to radio transmitter problems This paper comprised an account of the work carried out by the Radio Section of the Post Office between 1925 and 1934 in the development of the use of quartz crystal oscillators in a number of different applications, of which the most important was the control of the carrier frequency of short-wave transmitters employed for overseas radio services A description was given of the results of a comprehensive investigation of the chief characteristics of different types of quartz crystals, and the manner in which they must be used in order to secure the highest constancy of frequency Particular attention has been paid to the effect of temperature on the frequency of the crystal oscillator, and special constant-temperature ovens have been designed for the oscillators used for the control of transmitters operating commercial radio-telephone services The concluding section of the paper gave the results of a study of the performance of frequency-controlled transmitters in actual service. The graphical records show that it is possible to keep the frequency of a transmitter under strict control for periods up to two years, during which it is only on rare occasions that the variations exceed the limits of tolerance set by international agreement

Chemistry of Fats. Prof T P Hilditch (*Chemistry and Industry*, **54**, 139, 163, 184, 1935), in his Jubilee Memorial Lecture to the Society of Chemical Industry, directed attention to recent investigations of the chemical composition of fats It had been assumed that the normal constituents of fats and oils were tristearin, tripalmitin and triolein, other substances being regarded as abnormal It is now known that some of the supposed fatty acids are mixtures of two other acids in equimolecular proportions, margaric acid, for example, consisting of palmitic and stearic acids Again, the assumption that simple triglycerides (containing three identical fatty acid radicals) are predominant is incorrect in the natural fats the triglycerides are usually mixed The major component acids of a fat often exceed three and may be as many as ten or twelve in number, and their relative proportions vary widely in different cases In the case of fruit-coat fats, the major component acids are practically only palmitic, oleic and linoleic acids, but in many other seed fats, other quite specific acids are found Cruciferous seed-fats, for example, contain large quantities of the unsaturated erucic acid, Umbelliferæ contain petroselinic acid (an isomer of oleic acid), etc What Prof Hilditch calls an 'even distribution' rule appears to operate in regulating the composition of the glycerides A number of general questions, such as the conversion of carbohydrates into fat in living organisms, and the catalytic hydrogenation of fats, were also considered.

Effect of Ozone on Rubber Insulated Cables. It has been well known for many years that ozone attacks rubber, producing cracks and so destroying its insulating properties The father of the present Lord Rayleigh used to show an experiment at the Royal Institution illustrating this effect A sheet of stretched rubber was put several feet away from the spark gap of an induction coil which was then started working After a few seconds, a hole appeared in the stretched rubber which rapidly increased in size It will be seen that it is necessary when working with the coronal and brush discharges which appear at high voltages to shield rubber cables In the *Electrician* of February 22, the method of testing cables used by the German Aircraft Research Establishment to see the effects of the action of ozone is described It appears that the ignition cables of aeroplane engines have to be renewed every 400 hours due to deterioration produced by ozone. In 1932 a German cable manufacturer succeeded in producing a rubber compound which was practically unaffected by ozone under normal working conditions A cable insulated with this new compound was subjected to the action of ozone for 1,000 hours and then passed satisfactory tests A cable insulated with ordinary rubber broke down after one hour's similar treatment. Typical examples of test pieces after breakdown are shown. It is stated that with ordinary ignition cable, corona discharge begins when the crest value of the voltage is 7,000. Under normal conditions the crest value is double this, and to prevent its formation it would be necessary to increase its diameter from 0·28 in. to 0·44 in., which would require 2·5 times as much material.

Mechanism of Salt Absorption by Plant Cells

By F. C. STEWARD, Birkbeck College, University of London

FEW problems in plant physiology have more general implications than that of the mechanism of salt absorption. The outstanding feature which requires explanation is the means whereby certain salts, which occur in extreme dilution in the medium bathing the cells, attain considerable concentrations in the vacuole, where they are maintained, apparently, in true solution. The obvious analogy between this process and the mechanism of secretion in the animal body is alone adequate justification for again directing attention to this question.

In recent years there have been many physico-chemical speculations which suggest devices whereby living plant cells might evade those simple equilibrium conditions which they rapidly approach after death or injury. The tendency has been to stress mainly the properties (real or hypothetical) of the functional membranes, and to pay but scant attention to the metabolic activities of the living system. One of the most prominent of such theories is still that of Osterhout[1,2]. The principal features of this view and those relevant to this discussion are as follows:

(1) The functional protoplasmic membranes are fluid, lipoidal and non-dissociating.

(2) Salts enter principally, if not exclusively, as undissociated molecules. Cations penetrate only in association with hydroxyl in the form of undissociated free base.

(3) The gradient of 'thermodynamic potential' of free base ([K] × [OH], [Na] × [OH]) determines the rate and direction of movement of K and Na respectively.

The theory is largely based upon experiments with the marine cœnocytic green alga, *Valonia macrophysa*, which, like the closely related form *Valonia ventricosa*, occurs in warm seas under highly specialised conditions of light, temperature and aeration.

V. macrophysa occurs at Bermuda and has been investigated mainly in winter, whereas both species are found at Tortugas, either in the specialised environment provided by the moat of Fort Jefferson (mainly *V. macrophysa*) or on the open reef (*V. ventricosa*). The Tortugas material has been examined in the summer months and the criticism has been raised by the workers at Bermuda that it is not 'healthy' at this season. This is not borne out by my own experience, especially in the case of *V. ventricosa*, which is on morphological grounds the most useful species.

In recent years the theoretical views have also been developed by experiments on 'models'[3,4] purporting to represent the living cell, on the implicit assumption that the fundamental postulates are correct. In the light of recent work, one may query this from two points of view, namely:

(1) That the theory is not an adequate explanation even for the special case of *Valonia*.

(2) That it exploits unduly the peculiar features of *Valonia* and its environment in a manner which could not possibly apply to plant cells in general.

Until recently[5], the direct evidence for the theory has rested largely upon experiments in which the *internal* reaction of *Valonia* was modified by the penetration of ammonium hydroxide from ammonium chloride - sea-water[6]. Granted that the theory accounts qualitatively for the *direction* of the subsequent movement of potassium and sodium ions (K out, Na in) it is evident that it cannot account for rates. Contrary to expectations, sodium enters in presence of ammonium chloride much faster than in normal sea water. Furthermore, in this experiment, one of the most significant of those which test the theory on *living cells*, rather than models, the observed change in sap composition is in the direction of attainment of equality of concentration between sap and external solution. Consequently, potassium and sodium ions each moved *with*, rather than against, the prevalent gradients, not only of potassium hydroxide and sodium hydroxide but also of the respective ions. The crucial test of the theory is its ability to explain and foretell movements in the *reverse* direction. Despite attempts to evade this objection (see ref. 6, p. 310), it seems that the more probable explanation is that the ammonium hydroxide produced changes for which injury is the only, but unsatisfactory, designation. That ammonium chloride in the concentrations employed has such irreversible effects upon *both* species of *Valonia* (*V. macrophysa* and *ventricosa*) as they occur at Tortugas is now quite evident[8,9]. Unless differences between the Tortugas and Bermuda types of *V. macrophysa* without morphological or taxonomic basis are postulated, it is difficult to believe that such did not apply in the earlier experiments of Osterhout[6]. This is in fact indicated, since some cells were actually so far from normal that they died, and considerable corrections were necessary in the volume data of the ammonium chloride series (see ref. 6, pp. 308, 309). In the light of this the evidence that the remainder were completely uninjured is not convincing.

Recent experiments[10] with potato tissue which imitated the essential features of the above *Valonia* experiments have shown that the effect of ammonium penetration from ammonium salts is to reduce the capacity for the accumulation of *all ions*, namely (K, Na, Cl, Br, phosphate), and this is reflected in decreased water absorption. This occurred although considerable internal concentrations of ammonium produced only a small change of internal *p*H in the more strongly buffered cell sap of potato. The penetration of ammonium seems to depress the accumulation mechanism. Any other superimposed effects were readily interpreted as simple exchanges involving cations.

Experiments involving ammonium chloride solutions are therefore but a dubious proof of the theory of Osterhout, although from the prominence given to them[1,2] they are apparently regarded as its best confirmation.

The theory in question also demands that changes in external reaction, as well as internal, should affect the distribution of potassium and sodium ions between sap and sea water. Considerable prominence has been given to the fact that an external *p*H of 5·5, which causes irreversible injury and death, also induces loss of potassium ions. For reasons already stated, this has little or no value as a confirmation of the mechanism of *accumulation*. Jacques and Osterhout[5] also claim that a recent examination of the effects of external reaction substantiates the theory. It is again apparent that very small

concentration changes have been transformed by using volume data to what appear to be considerable differences of *total amount* In other words, there is no evidence that the internal *concentration* of potassium ions is a function of external *p*H, but rather to the contrary If the external *p*H really does determine the growth of the cells and hence the total salt content, this is not necessarily a proof of the suggested mechanism of entry and accumulation of potassium ions, but merely another indication of the connexion between the processes of growth and metabolism and that of salt absorption. Unfortunately, the most significant data refer to experiments in the light, where there is considerable uncertainty as to the exact *p*H which prevailed and the nature and extent of its drift[5] The apparently large magnitude of the suggested difference in absorption of potassium ions (see ref 5, Fig 1), which is attributed to the small difference in *p*H between two cultures (one of *p*H 8 8 and the other which "started at 8·2 and rose somewhat but apparently not as high as the other"), strongly suggests to me that some other variable and not the concentration of hydroxyl ions was really the determining factor in this case This is the more probable when one recalls that, though this organism in its normal habitat may withstand considerable fluctuations (diurnal and otherwise) of certain factors (oxygen concentration, external *p*H, etc), yet in its growth and distribution it is clearly limited by subtle differences not easy to specify completely This has been impressed upon me by observations in the moat of Fort Jefferson at Tortugas Attempts to demonstrate the effect of external *p*H upon the absorption of potassium ions by *Valonia macrophysa* in the dark were inconclusive One of the reasons suggested may be incorrect since, contrary to the statement that it lacks carbohydrate, *Valonia* may be abundantly supplied with small starch grains[11]

Fortunately, quite apart from its ability to grow conspicuously, *Valonia ventricosa* (not available at Bermuda) will absorb potassium from sea water enriched with potassium chloride either in the dark or the light External *p*H's ranging from 9 0 to 5·5 may be produced and maintained by control of the carbon dioxide tension. Under these conditions, it is now apparent[8,11] that an approximately threefold increase of external concentration of potassium ions can produce a definitely significant gain by the cells both of concentration and total amount, and this is but slightly affected by an external *p*H range from 9 0 to a reaction only slightly more alkaline than 5 5 Moreover, a slight but significant maximum occurred not at *p*H 9·0 (as the theory referred to would demand) but at approximately *p*H 7·0. The theory of 'thermodynamic potentials of free base' demands that the tendency for potassium entry, measured by the value of the product [K] × [OH] for external surroundings should be determined equally by the concentration of the potassium and hydroxyl ions It appears, therefore, that entry of potassium is more closely related to the potassium ion concentration than the hypothetical [KOH]. Similarly, when sea-water is enriched with sodium chloride, some gain of potassium may be observed, which also suggests a closer relation between potassium absorption and [Cl] than [OH], since the [KOH] remained undisturbed[11]

It is submitted that these facts are in accord with other views which show that the rôle of *p*H is not the dominant one which the theory suggests. Hoagland[12], using both *Nitella* and the roots of barley, has shown repeatedly that they can accumulate both ions (for example, potassium and bromide) from solutions more acid than the vacuole Similarly, I have stressed that the existing *p*H gradients could not explain the behaviour of storage tissues, which accumulate salts from solutions almost identical in reaction with their cell sap Such facts controvert the theory of Osterhout In view of its dubious utility in the interpretation of the special case of *Valonia* and the abundant evidence to the contrary, especially where more active systems are concerned, there seems to be little justification for continued emphasis upon the idea that cations (particularly potassium and sodium) penetrate cells in general only in the form of undissociated free base

The experiments at Tortugas, already referred to, suggest that the obscurity which surrounds the manner of growth of *Valonia* and the extremely low level of its metabolic activity more than outweigh its apparent morphological advantages That the latter are more apparent than real is suggested by even a casual experience with these organisms It is an interesting anomaly, both morphologically and physiologically, rather than a typical case from which generalisations may be drawn safely To my mind, *Valonia* finds its parallel with cells like red blood cells or those storage tissues which have permanently ceased active growth and synthesis, rather than the more vigorously metabolising plant cells like those of rapidly growing roots or certain storage tissues[7] which display greater capacity for salt absorption In the latter cases, it is still difficult to avoid the view that cells do osmotic work in the simultaneous absorption of both anions and cations by virtue of their metabolism and capacity to grow Nor does the rôle of growth merely involve cellulose synthesis and wall extension, but rather is the ability for salt accumulation inherently a property of cells still capable of constructive protein metabolism and a turnover of carbohydrate far in excess of that involved in mere cellulose synthesis. Thin discs of potato tissue in dilute aerated solutions of potassium salts may metabolise carbohydrate equivalent to 4 27 kgm cal per 45 gm. fresh weight in three days. This is equivalent approximately to one sixth of their original total heat value, and most of this decrease in total energy may be due to heat production. Whether a fraction not yet accounted for is more specifically associated with accumulation of salts is a problem at present under investigation.

Whatever the rôle of carbohydrate metabolism may prove to be, it is difficult to follow Osterhout so far as to believe that, if the necessary metabolic activity were available, the still extensible walls of *Valonia* could not be distended without cellulose synthesis, so that further increment of salt *concentration* (without corresponding water absorption) could be accommodated by an increase of wall pressure Despite even the evidence of slow cell extension[5] in the recent Bermuda experiments, it seems that the large cells of *Valonia* as commonly used retain the essential properties only in relatively slight degree Consequently, the rôle of respiration and metabolism as a potential source of energy has been minimised and the chief stress laid upon its possible effect as a determinant of internal reactions. The theoretical manipulations of ionic products (for example, [K] × [OH] ; [Na] × [OH]) are based essentially on equilibrium criteria and create the illusion that rapid metabolism and energy exchanges are

unnecessary for salt accumulation *per se*. It is in these operations that undue weight seems to have been given to certain special features, not applicable to cells in general, of what is after all an obscure organism

Lastly, there seems grave danger that the admittedly ingenious and extensive work devoted to models[3] may divert attention from the fundamental facts that, not only are they far removed from physiological reality, but also that the very principles upon which they are based are such that judgment must be reserved concerning their applicability to the general problem of salt absorption *in vivo*

Conference on Industrial Physics

THE first Conference on Industrial Physics to be held in Great Britain took place in Manchester under the auspices of the Institute of Physics on March 28–30 The subject chosen for the Conference was "Vacuum Devices in Research and Industry", and its chief object was to direct attention to the important part which physics and physicists can and do play in modern industrial life Nearly six hundred people registered as members of the Conference, of which about a hundred were members of the Institute The majority of the others were engaged in Government and industrial research laboratories and works, some coming from a considerable distance to attend the meetings The outstanding success of this new venture of the Institute of Physics has demonstrated beyond all possible doubt that there exists a very large number of men who are engaged in applying physics to the solution of industrial problems, in addition to many who are employing its methods for industrial work of a more routine character One of the objects of the Institute is to provide facilities for the interchange of ideas among those engaged on industrial physics problems by means of meetings and special journals Many propositions towards the achievement of those objects will doubtless come to earlier fruition as a direct result of this Conference

The sessions were held in the University of Manchester. The Conference was formally opened by Sir William Clare Lees and the Vice-Chancellor, and was presided over by Prof W L Bragg The lectures were all informal in character, and consequently they are not being published, each lecture was followed by a useful discussion The titles and lecturers were as follows "Modern Electrical Illuminating Devices" by Mr J. W. Ryde, of the General Electric Co Ltd, "Applications of Photocells" by Mr. T M. C Lance, of Messrs. Baird Television Ltd, and Mr. R C Walker, of the General Electric Co Ltd, "The Cathode Ray Oscillograph in Research and Industry" by Mr L. H Bedford, of Messrs A C Cossor Ltd; "Recent Applications of Mercury Vapour Rectifiers and Thyratrons" by Mr L J Davies and Mr. A. L. Whiteley, of the British Thomson-Houston Co Ltd, "High Tension Vacuum Tube Devices in Research and Industry" by Dr J. D. Cockcroft, of the Cavendish Laboratory, Cambridge; "X-rays in Industry" by Dr. G Shearer, of the National Physical Laboratory It was interesting to record that, almost without exception, those who took a leading part in the various activities of the Conference, including the lecturers, were quite young men The Organising Committee also received considerable commendation for its care in the selection of the lecturers, who were in each instance associated with industrial practice, the Committee preferred to extend the invitations to lecture to such men rather than to distinguished pioneers of the devices who, it was felt, would be more familiar with them in the laboratory stage, as distinct from their adaptation for industrial purposes

On March 29 the members of the Conference spent the afternoon at the research laboratories and works of Messrs Metropolitan-Vickers Electrical Co Ltd, and the next day visits were paid to the Shirley Institute of the British Cotton Industry Research Association, and to the Post Office Telephones

An exhibition of apparatus, instruments and books cognate to the subject of the Conference was held in the laboratories of the University, in which twenty firms and research organisations took part, and in addition some of the important work which is being carried on in the physical laboratories of the University was demonstrated A special section intended to exemplify the multifarious uses and utilitarian value of vacuum devices was a feature of the exhibition, and aroused great interest The specific function of the whole exhibition was to demonstrate that apparatus such as the cathode ray tube and the photocell, for example, are now utilised in devices which are practically fool-proof and can be used as tools in all manner of manufacturing processes Unlike other exhibitions, it was not so much concerned with demonstrating the underlying physical principles of instruments or details of their mechanism, but rather with the fact that the devices shown were not more scientific toys that had been brought from the laboratory and disguised, but that these devices were real and necessary industrial tools, which the more enterprising manufacturers are already employing A limited number of copies of the catalogue of the exhibition is still available from the Institute of Physics, London, S W 7 (1s 3d post free)

On Saturday morning some 65 parties from local schools visited the exhibition, and in the afternoon and evening it was thrown open to the public It is estimated that 3,500 people visited the exhibition during the three days

Prof W L Bragg broadcast a talk about the

Conference and exhibition on the evening of March 29 and it also received considerable attention from the Press On Friday evening, March 29, Mr R A Watson Watt delivered a public lecture, which was attended by about 350 people, on "Cathode Ray Tubes in Industry" The lecture was given in the Great Hall of the College of Technology It is hoped, in these ways, to bring to the notice of all, the great possibilities of existing inventions and scientific knowledge of a physical character, and the important part which these play in everyday life

The social events included a Conference dinner in the College of Technology, at which Sir Henry G Lyons, the president of the Institute, presided, and the guests included the Lord Mayor and the Lady Mayoress of Manchester, and a number of other distinguished persons

The great success of this Conference renders it likely that similar conferences will be held from time to time in the future Apart from the value of the information gained from the various lectures and discussions, as well as from the exhibition and the visits, the contacts made between physicists and those concerned with the technical developments of industry cannot but prove a fruitful source of lasting mutual benefit HERBERT R LANG

University Education

THE inaugural address of the president of the Royal Statistical Society, Prof M Greenwood, delivered on November 20, 1934, contained many points of interest concerning the past history and probable future of the universities of Great Britain (*J Roy Statistical Soc*, 98, 1-37, 1935)

By consideration of birth-rates, there should be a decline in numbers at the universities in 1935-36, a recovery in 1938-9, and then, unless there is a change of policy, a steady decline The present entrance requirements are not unduly severe, in fact, if we adopt the view of some university teachers, that failure to obtain first or second class honours shows unsuitability for university training, more than fifty per cent of the unassisted students should have been excluded, and also 10 25 per cent of those assisted by scholarships and similar benefactions Dr A Flexner, who considers that a university suitable for the present and future of the world should be concerned with the conservation and interpretation of knowledge and ideas, the search for truth, and the training of students, concedes that Oxford and Cambridge have touched the fringe of these ideals, but he finds it impossible to give even this faint praise to any other English university, least of all to London Mr H. G Wells doubts whether the universities and the conceptions of education they embody are destined to any very prolonged predominance over the intellectual processes of mankind, and considers the ordinary arts course in our older universities to be "merely a wasteful prolongation of puerility". Even Dr H Rashdall, who cannot be accused of prejudice against the ancient universities, observes that "Universities have often had the effect of prolonging and stereotyping ideas and modes of thought for a century or more after the rest of the world has given them up"

However, Prof Greenwood considers that Dr Flexner's ideals are too narrow, and are capable of realisation only in small and cloistered communities like Oxford and Cambridge For large cities such as London, he considers that the loss of intimacy may be compensated by a gain in continuity, and that requirements should be made less rigid, so as to have no chasms between matriculated and non-matriculated students, or between graduates and non-graduates In the past, one supported education largely on the ground that an educated nation would be better fitted to secure advantages in the international struggle for markets But there has been a fundamental change in economic conditions Now that productive man power is in excess of demand, and millions of man-hours are running to waste, higher education should be considered, not for the material or social advantage it confers, but as a path to happiness

In the discussion that followed the address, Mr Udny Yule deprecated some of the sterner judgments on the University of London, and suggested that it differs from the older universities in degree rather than in kind The research worker is the evolutionary successor of the hunter and is not a being apart, stripped of emotion, an intellectual machine On this view we can understand his psychology, his blunders, his emotions In fact, it is impossible to draw a sharp line between the investigations of a detective and those of the best type of fellow of the Royal Society Even a poor piece of investigation may have taught much to the investigator himself, and have given him many happy hours

University and Educational Intelligence

LONDON -Dr John Gray, since 1934 director of pathology and Lyle research scholar at Queen Mary's Hospital for the East End, has been appointed reader in morbid anatomy at the British Postgraduate Medical School, as from April 1

On his retirement from the professorship of surgery at St Bartholomew's Hospital Medical College at the end of the present session, the title of emeritus professor in surgery in the University will be conferred on Prof G E Gask

The Senate has approved a proposal to hold the School Examinations (General School and Higher School) overseas in and after 1936

ST ANDREWS -The Senatus Academicus has resolved to confer honorary degrees on the following, among others, *LL D*, the Right Hon. Lord Alness, Andrew Bennett, secretary of the University since 1903, and secretary of the Scottish Universities Entrance Board, Prof C H Browning, Gardiner professor of bacteriology in the University of Glasgow, Prof A H Gibson, Beyer professor of engineering and director of the Whitworth Laboratories in the Victoria University of Manchester, Sir John Boyd Orr, director of the Rowett Institute, Aberdeen

THE Fifth Quinquennial Congress of Universities of the Empire, organised by the Universities Bureau of the British Empire, will be held at Cambridge on July 13-17, 1936

UNIVERSITY education in the United States is breaking free from the traditional system of semester-hour credits with compulsory class attendance and teaching by textbooks More than a hundred universities and colleges have, says Dr. McNeely of

the Federal Office of Education in a paper contributed to *School and Society*, adopted in varying degrees devices for substituting voluntary learning on the part of the student for external compulsion. Among the leaders are the University of Chicago, Harvard, Cornell and Buffalo Universities and Swarthmore and Goucher Colleges.

OF German professors expatriated owing to Nazi intolerance, thirty four have, it appears, migrated to the United States, and sixteen of them have been assigned to various universities by an "Emergency Committee in Aid of Displaced German Scholars". The remainder have combined in New York to form under the leadership of Dr. Alvin Johnson, director of the New School for Social Research, an association known as "The University in Exile". An article in *School and Society* of February 23 announces the appointment of a permanent board of trustees for the association. The association aims at perpetuating "the free German culture, which it had become traditional that post-graduate students from America and all over the world should seek, as a complement to the facilities of their own lands": the words are quoted from a statement by the chairman of the board, Mr. I. A. Hirschmann.

THE Royal Institute of Science, Bombay, which began teaching work in 1920, has recently issued a report (Bombay: Government Central Press, pp. 74, gratis) covering the period 1926–34. The declared policy of the Institute has been (1) to interest the public by popular lectures and demonstrations, (2) to qualify undergraduates for scientific investigation, (3) to provide the means for carrying out original work, to guide beginners in research and to co-operate, on occasion, with other scientific institutions and assist industry by investigating industrial problems. The staff comprises, in addition to the principal, Dr. T. S. Wheeler, sometime senior research chemist with Imperial Chemical Industries, Ltd., eighteen professors, lecturers and demonstrators in chemistry, physics, botany, zoology and mathematics. The students, excluding courses in physics for first-year arts students, number about 300 and the annual cost of their education is Rupees 608 per student. There has been in the past ten years a steady increase from 26 (being 15 per cent of all full-time students) to 91 (31 per cent) in the number of post-graduate students. Progress in developing the Institute's research activities is further indicated in a list of 128 papers published and abstracts of 101 researches in progress. Both staff and students are, the report says, keen on their work, and the library and laboratories are open until late in the evening, even during vacations. A frontispiece to the report gives a view of the impressive façade, 400 yards long, of the Institute building, a wing of which was handed over in November 1933 to the University of Bombay to house the new University Department of Chemical Technology.

Science News a Century Ago

Monument to Telford

In *The Times* for Tuesday, April 7, 1835, it was stated that "At a general meeting of the Dundee Harbour Trustees on Wednesday last, it was moved by Mr. David Baxter that the harbour trustees do subscribe 10 guineas to the general subscription in London for a monument to the memory of Thomas Telford, Esq., Engineer, to be erected in Westminster Abbey, in consideration of the valuable services rendered by that distinguished engineer to the harbour of Dundee, first, in giving the very excellent plan for the construction of the first wet dock now called King William's dock; 2nd, in the valuable professional and practical advice which he gave for carrying the work into effect; 3rd, in procuring from Government, by the Exchequer Loan Commissioners, at a time when the erection of the harbour was considered to be a work of speculation, a loan of the sum of £30,000 (nearly all this has since been repaid); and lastly, for giving his able assistance in carrying the perpetual bill of 1830 through Parliament, which has placed the harbour establishment in a situation that has made it at once the cheapest and one of the most improved harbours in this kingdom."

Lardner on Halley's Comet

On April 10, 1835, Lardner gave the first of two lectures on Halley's comet at the Royal Institution. In the course of his lecture, he said that in 1757 Lalande proposed to Clairaut the calculation of Halley's comet, which was expected to return shortly. They were assisted by a French lady, the wife of a chronometer maker. The calculation was enormous, because the orbit must be divided into degrees, and each degree required as great a calculation as the whole orbit. They tell us, he said, that they were employed from morning to night, not excepting meal hours, incessantly for six months in this computation. Clairaut was so nervous that he hurried his calculations before the Institute. "Although Clairaut was not quite correct to the day, the only wonder was, that he should have been so accurate, for as he said, when a body traverses a space of 1,500,000,000 miles beyond our sphere of observation, how do we know but that some other planet may act upon it, and influence its course. In 25 years the planet Herschel was discovered, which it was proved, did actually operate in producing the effect which Clairaut had surmised."

Railways in France

According to the *Mechanics' Magazine* for April 11, 1835, the French Minister, M. Thiers, had just presented to the Chamber of Deputies "a project of law relating to railroads. He announced that the Government engineers had fixed upon three principal lines for railroads—one from Paris to Havre, via St. Denis, Pontoise, and Gisors, with branch lines to Rouen and Dieppe; a second from Paris to Lyons and Marseilles; and a third from Paris to Lille, Bourdeaux and Strasbourg. Surveys have it appears been made, and plans drawn out for these three several lines; but one only, that from Paris to Havre, is recommended to be at first undertaken. It is proposed to throw open the work to public competition, and to entrust it to any company who will offer the best conditions, and sufficient securities." A fortnight later the *Mechanics' Magazine* said that there were in operation in France railroads from St. Etienne to the Loire (thirteen miles), St. Etienne to Lyons (thirty-seven miles) and Andrezieux to Roane (forty two miles), while two other lines under construction ran from Alais to Beaucaire (forty-three miles) and from Epiney to the Canal of Burgundy (seventeen miles).

Societies and Academies

EDINBURGH

Royal Society, March 4 A. M COCKBURN · The geology of St. Kilda. The islands of the St. Kilda group appear to represent the peripheral relics of a larger complex of intrusive igneous rocks perhaps some seven miles in diameter The intrusions are sheet-like and, in order of age, consist of gabbros (including olivine eucrite), coarse- and fine grained dolerites, basalts and three granophyres. On St Kilda these masses, the eucrite excepted, are inclined outwards from the supposed centre of intrusion, suggesting ring dyke structure A very abundant series of variously dated, thin, gently inclined sheets are suggestive of cone intrusion. Arcuate structure, however, has not been observed in the field owing to the fragmentary nature of the exposures J. L. BHADURI The anatomy of the adhesive apparatus in the tadpoles of *Rana afghana*, Günther, with special reference to the adaptive modifications A histological description of the cement organs is given and attention is directed to the 'brush-border' fringing the gland cells The muscles of the disc are described and their homologies discussed The diaphragm is shown to be modified, not only has it a thickened tendinous ridge in its central part, but in addition it possesses two distinct apertures for the passage of the diaphragmatobranchialis medialis muscles An account of the histology of the skin of the disc is given The cornification, and later tuberculation, of the posterior region of the disc is shown to be correlated with the habits and habitats of the tadpoles The rim of the sucking disc encloses a lymph space which is considered to be another adaptive modification for counteracting the pressure of the rushing current A C AITKEN · Least squares and linear combination of observations The paper deals with the equivalence, in practical outcome, of two different approaches to least squares, one based on the assumption that errors are normally distributed in such a way as to give the observations the greatest probability, the other on the postulate that the values to be adopted should be weighted means of the observations, with smallest standard error Dr W. F. Sheppard had proved this equivalence for representation by polynomial curves The present paper confirms it for general functional representation, as well as for the case of correlated errors

Road Traffic Research

THE heavy toll of accidents on the roads in Great Britain, averaging at present about 20 fatal accidents and 590 non-fatal accidents a day, has at last thoroughly aroused public opinion, and the recent imposition of a speed limit of 30 miles an hour in built-up areas is the latest attempt to reduce the appalling toll of these accidents Important as the question of accidents may be, it is not the crux of the road traffic problem, and as Mr Mervyn O'Gorman pointed out in his lecture to the British Science Guild last December, which has recently been made available as a pamphlet*, an approach to the problem from this angle may lead to serious if not highly dangerous errors

The critical factor is the relation of road accidents to the magnitude and importance of road transport as a whole The figures supplied by Dr K G Fenelon in his paper to the Royal Statistical Society on February 19 show that in the sixteen years since the War, road transport has developed out of all recognition, and has had repercussions on the whole economic and social structure of Great Britain It is already one of our major industries, providing a livelihood for 690,000 persons In 1933, more than $2\frac{1}{4}$ million motor vehicles were in use, something like a quarter million workers were employed in the construction and repair of motor vehicles , exports produced by the motor industries amounted to about twelve million pounds sterling, 5,400 million passenger-journeys were undertaken on public service road vehicles which operated some 1,300 million vehicle miles About fifty-four million pounds sterling were expended on highways and bridges, and nearly sixty-nine million pounds gross were raised from motor taxation of all kinds

Motor transport is thus firmly established as an essential and co-ordinate part of our national transport system, and not as a mere subsidiary or auxiliary of the older forms of transport It is as much a public utility service as water supply or drainage, but as yet there has been no corresponding expenditure from the revenue raised from the industry on the scientific research essential for determining the adequate quantity of roads, their economic lay-out or the wise control and guarding of the traffic. Mr O'Gorman's plea for the scientific study of the traffic problem gives a

* Bringing Science into the Road Traffic Problem. By Lieut.-Colonel Mervyn O'Gorman. Pp 36. (London British Science Guild 1935) 1s

picture of the services which science can render and of the dangers which attend legislation based on unscientific or haphazard experiment

The tragic position of the road traffic problem at the moment and the sterility of all attempts to diminish accidents, whether by motor control, registration, insuring, licensing or deterrent enactments, are due primarily to the omission to base legislation on scientific experiment and definite facts. In the absence of such study, well-intentioned legislation is apt to have consequences and repercussions widely different from or even opposed to those for which it was designed It is no longer rational to regard road transport as mainly competitive with the railways It is a complementary system providing a flexibility of paramount importance to certain classes of goods and industry, and any attack on the accident problem which impairs the efficiency of road transport as a whole might well be a national disaster

Despite the attention directed to road transport in the last few months, opinions as to the goal at which we are aiming or the improvements to be effected are often confused, and agreement as to what constitutes improvement has yet to be secured The subject is often discussed as if the mere reduction of accidents, irrespective of the volume of road traffic, were an end in itself, even if achieved by driving all traffic off the roads No more important point was made by Mr O'Gorman than his suggestion that our objective is to obtain an ever-diminishing fatality ratio, and only to achieve this under conditions or rules which will not block whatever expansion of safe road traffic the economy of the State may require from time to time

In the wide field for investigation which road traffic offers, certain subjects such as the examination of drivers, dazzle road illumination, skidding, noise, vibration, emission of dangerous fumes, are patently subjects for study by experiments conducted under disinterested scientific guidance, and investigations in this field are already being fostered by the Department of Scientific and Industrial Research at the Road Research Station and elsewhere In many problems, however, even the technique for acquiring data has yet to be evolved, and when the requisite data have been acquired there is the problem of securing uniform action on the part of the many authorities concerned, so that the advantages of a scientific policy may be secured for the whole country and not endangered by a recalcitrant or backward minority.

At the present time, the acquisition of data is the first necessity. The existing expenditure on road research, amounting to the very inadequate sum of £30,000, is devoted to road construction and materials; the cost of the research really required should be considered in relation not merely to the magnitude of road transport alone as a major industry, but also in regard to the estimates of the cost to industry as a whole of road transport accidents, loss in traffic delays, etc The cost of the committee and experimental work visualised by Mr O'Gorman would be infinitesimal in comparison with the outlay on research in the expenditure of any well-run factory if its income was scaled up to £71,000,000 For 1933, the loss to the community through the 191,782 road casualties is estimated at £30,000,000, and for London alone it is estimated that traffic delays cause a loss of £20,000,000 a year

It is in the light of such figures as these that the community must assess its capacity for expenditure on the fundamental research, and it should be noted that the solution of many of the more pressing problems is intimately related to questions of taxation, whether in the form of differential duties on heavier or lighter road vehicles or on land valuation and urban development Moreover, the unmixing of experiments which direction by a competent committee would ensure, and the planning of investigations to relate particular results with particular factors, would eliminate a good deal of the present waste of effort and money on experiments in which numerous factors are being varied simultaneously

To take only one example of these relations, a sound decision on the taxation of 12-ton lorries in favour of 3-ton vehicles depends on the effect on road safety of the increased traffic density induced thereby, the effect on the general fluidity of road transport, whether additional road construction is necessitated by the increased traffic density and the difference in road wear due to the 12-ton lorry in comparison with the 3-ton lorry. The answers to such questions are urgently demanded to-day, and they involve measurements of the effect of increments of traffic density on accident incidence and traffic flow, as well as that of total vehicle weight and speed on road maintenance. Cardinal to them is an instrument and a system for recording increments of traffic flow, and until we have set our hands to the evolution of scientific methods

for measuring and recording traffic flow, traffic density and traffic accidents, our efforts at accident prevention are likely to revolve in a vicious circle with more and more serious effects on our national economy

Almost the whole of our expenditure, national and local, on the control of cross-road traffic, on ribbon building along arterial roads, or on traffic regulation whether of lighting, orderliness or speed, including the punitive question, is liable to be fruitless for absence of the groundwork of definite facts on which to base wise decisions It is possible of course for sound decisions to be taken fortuitously in the absence of such knowledge It is equally possible for disastrous mistakes to be made, and no scientific worker can rest content with a situation in which wise or foolish action is determined by blind chance when the means for acquiring the fundamental information are to hand

It is, of course, idle to pretend that the establishment of such a committee as that urged by Mr O'Gorman would immediately yield even a fraction of the data required Probably twenty-five years would be required before the full data were available to justify or condemn the many so-called experiments at legislative control in operation to-day None the less, systematic work under a scientific programme would assuredly yield results capable of practical application and increasing in value as accurate knowledge was built up of the laws of traffic flow Mr O'Gorman's plea for accurate measurements in this mode of road traffic and for their scientific correlation and analysis is one which should have the insistent support of every scientific worker

Reviews

The Problem of Chemical Linkage

The Electronic Theory of Chemistry: an Introductory Account. By Prof Robert Fergus Hunter Pp vii+125 (London: Edward Arnold and Co., 1934.) 8s 6d. net.

In contrast to a recent paper by Hunter and Samuel[1], which has been criticised even more adversely by physicists than by chemists[2], Prof. Hunter's book on "The Electronic Theory of Chemistry" is a trustworthy guide to modern views on the theory of valency, since it is very largely descriptive in character, and is more concerned with chemical facts than with physical theories The chief fault that can be attributed to the book is a lack of historical perspective, which gives to it a flavour of immaturity. For this fault, geographical limitations may perhaps be held responsible. Thus it is unlikely that the *Zeitschrift fur anorganische Chemie* for 1893 is readily available in Aligarh, and it is difficult to discover evidence that the author had this volume before him when he wrote his account of Werner's theory of co-ordination, which is there expressed much more clearly than in his subsequent book The author also omits to point out that the ideas of stable shells of electrons, and of chemical combination between atoms resulting either from electron transfer or from electron sharing, were introduced by J. J. Thomson[3] in 1907, and that their development in 1916 by Kossel and by G. N. Lewis respectively did not depend directly on the introduction of the nucleus atom in place of Thomson's model, but was an immediate sequel to Moseley's experimental determination of atomic numbers, which provided a firm arithmetical basis for the two conceptions which Thomson had already introduced

Prof. Hunter is also apparently not aware that the term "intramolecular ionisation", which he uses at the beginning of chap iii, was introduced by J. J. Thomson[4] in 1914 to describe dipolar molecules in which the centroids of the + and − charges do not coincide, and was afterwards applied by the reviewer[5] to those cases in which integral charges can be postulated on different atoms on the same molecule There is no reference to the article in *Science*[6] in which Langmuir defined the *duplet* and contrasted *positive* and *negative valence* with *covalence* (the term covalency was *not* used by Langmuir). It is, therefore, perhaps not surprising that the author fails to attribute to Langmuir some of the fundamental ideas of the electronic theory of co-ordination, which were afterwards included in Sidgwick's theory, for example, the formation of a bond by the sharing of a duplet between platinum and ammonia, and the development in the compounds of the transition elements of large 'negative' valences, corresponding with Sidgwick's conception of 'effective atomic numbers'. No reference is given to the introduction of the terms 'ionotropy' and 'prototropy' in 1923, although a corresponding reference is given to the introduction of the terms 'anionotropy' and 'kationotropy' in 1931.

Whilst the main feature of the "electronic theory of chemistry" must always be the recognition of two main types of valency, as described

in the second chapter of the book now under review, five central chapters are devoted to possible variants on these two types The ball was set rolling by the reviewer[7] in 1922, when he first suggested that a 'mixed double bond' could be formed by superposing an electrovalence on a covalence, as represented by the symbol $\overset{+}{=}\!\!\!\!\!\!{}^{-}$ or $\overset{\rightharpoonup}{=}$, where the barb represents the direction of the field of force of the electrovalence Mixed triple and quadruple bonds were also postulated, but whilst the reviewer was responsible for *both* these symbols, Sugden alone was responsible for describing the preceding special case as a 'semi-polar double bond' Sidgwick afterwards used the symbol $\leftarrow$, with an arrow pointing in the opposite direction to the barb, to represent the formation of this type of linkage (which he described as a 'co-ordinate link'), by using the 'lone pair' of electrons of a 'donor', to make good the deficit of electrons of an 'acceptor', by sharing them between both atoms The reviewer's barb and Sidgwick's arrow are not inconvenient when applied to molecules, although an equation on p. 40 (in which two identical arrows mean quite different things) provides an excellent illustration of the more lethal character of Sidgwick's weapon, but in the formulation of ions, the scheme of localised + and − charges is the only one that is really convenient and quite free from ambiguity.

'Mixed' or 'semi-polar' double bonds were first postulated in 1922 in a paper on "The Polarity of Double Bonds"[7], as characteristic of the reactive forms of unsaturated organic compounds; and there is still no clearer method of formulating Lapworth's cyanhydrin reaction than by writing the equation:

The curved arrows, now generally used to express such processes as these, provide a convenient subterfuge for those who are shy of introducing ionic reactions into organic chemistry; but they are less easy to interpret, as any novice may discover by attempting to read an equation at the top of p 103, which looks like a long-chain molecule with an assortment of lateral substituents.

Localised electric charges in the same molecule have long been familiar in the betaines, $\overset{+}{N}Me_3\,CO.\overset{-}{O}$, and in the *o*-, *m*- and *p*-sulphanilic acids, $\overset{+}{N}H_3.C_6H_4\,SO_2\,\overset{-}{O}$, as an alternative to the use of grotesquely elongated bonds, running like telephone wires from one atom to another; but opposite charges on contiguous atoms in stable systems were first suggested in a paper on "Intramolecular Ionisation", published in 1923[8]. Charges of this kind were then postulated (i) in molecules such as the amine oxides and (ii) in ions such as the sulphate ion, for example:

The most interesting of these oxides are those which illustrate Langmuir's theory of isosterism, since this theory enables us to pass easily and safely from the formulæ

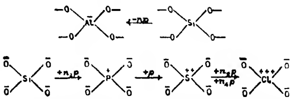
$$N\equiv N \text{ and } O=C=O \text{ to } \overset{-}{C}\;\overset{+}{O} \text{ and } \overset{-}{N}=\overset{+}{N}=O$$

Since the electronic shells in isosteric molecules are identical, these formulæ can be derived from one another by a process of *nuclear substitution*,

$$^{12}_{6}C + {}^{16}_{8}O \rightarrow 2\,{}^{14}_{7}N,$$

in which a neutron and a proton are transferred from one nucleus to the other, thus giving rise to the local + and − charges shown in the second pair of formulæ. In the same way, the borofluoride ion can be derived from the molecule of carbon tetrafluoride, by *removing* a proton from the carbon nucleus, whilst the ammonium ion can be derived from the molecule of methane by *adding* a proton and a neutron to the nucleus, which thus acquires a negative or positive charge respectively.

The same method can be applied to the giant molecule of silica and to the silicate ion, in order to justify the assignment of localised charges to the aluminium atoms of the aluminosilicates and to the central atoms of the phosphate, sulphate and perchlorate ions.



As Sidgwick has shown in the case of carbon monoxide[9], this nuclear substitution is not necessarily accompanied by the development of dipoles or quadripoles of equivalent magnitude, since the electronic system is flexible and can adjust itself, at least in part, to the new distribution of nuclear charges. The system of localised charges thus arrived at has been adopted on other grounds by Pauling and has been applied to crystal structures by W. L. Bragg and others, in a form in which, for example, a quarter of the field of the oxygen

atoms of the phosphate ion is directed inwards to balance the charge on the nucleus, so that only a net field of $-\frac{3}{4}e$ is available to balance the external positive ions. The author's statement that "the theory of the co-ordinate link lacks the sound physical basis which has been provided for normal covalency by wave mechanics" is therefore only partially justified, and recent work by Penney has removed the last justification for this discrimination in the case of the mixed bonds of the sulphate ion, where the distribution of charges derived from wave mechanics has been shown to correspond closely with that postulated by the reviewer in 1922.

It is a curious anomaly that the new ideas and formulæ of the electronic theory of chemistry, which the author describes so clearly and convincingly in the present volume, have been the subject of recantation in a recent paper by Hunter and Samuel, where a reversion to pre-electronic formulæ is urged "on the basis of wave-mechanics and band spectra" Since, however, the suggested theoretical basis for these retrograde proposals is regarded as inexact by those well qualified to judge, students may be advised to buy and read the present volume without risk of being misled by doing so.

Physics Teaching in Germany and Italy

(1) *Lehrbuch der Physik in elementarer Darstellung* Von Arnold Berliner. Fünfte Auflage Pp vii+736. (Berlin. Julius Springer, 1934) 19 80 gold marks.

(2) *Fisica Generale e Sperimentale* Per Prof Eligio Perucca Vol 1 · *Meccanica, Calore* Pp xvi+647 85 lire. Vol. 2 *Ottica, Elettricità e Magnetismo* Pp xv+870 110 lire. (Torino: Unione Tipografico-Editrice Torinese, 1932–1934)

(1) THERE has too often been a tendency in the past among writers of elementary textbooks of physics to present the subject in a fragmentary form, to discuss isolated details with great care but to avoid a discussion of the broad principles, as if this would endanger the sanity of the student by bringing him into contact with philosophy. Prof Berliner deserves our thanks for defining at the very outset of his well-known textbook the mechanistic basis on which he afterwards builds, and he wisely devotes great attention and considerable space to the underlying principles of mechanics For him, a physical law is a formula which describes rather than prescribes the behaviour of physical objects He explains why we find it expedient to seek the 'forces' that give rise to observed phenomena and points out the fundamental part played by motions Although the efforts to obtain a mechanical interpretation of electromagnetic phenomena have failed, a study of mechanics is still as essential to the student physicist as is a study of Bach to the aspiring modern musician

Early in the book, the student is introduced to the ideas of world-point and world-line, but the way in which they were originally applied by Minkowski is left over to a later section, where there is an illuminating account of the idea of physical relativity, both special and general The claims (on p 133) concerning the confirmation of the general theory of relativity are stated with exemplary caution It is doubtful whether there is in existence another elementary book of physics in which the background of the subject, to use Sir James Jeans's apt expression, is so carefully kept in view For a parallel we should have to turn to the far more advanced books of Planck Goethe has wisely said "es gibt Bücher, durch welche man alles erfährt und doch zuletzt von der Sache nichts begreift" The student who works through the present book, however, should have no difficulty in grasping the fundamentals of his subject.

New features in this fifth edition include the geometrical structure of solid bodies and the properties of X-rays The final chapter is entirely new, and is intended to serve as an introduction to atomic physics The author mentions in his preface that since this subject does not properly belong to a textbook for beginners, he has not passed beyond the picturable Rutherford-Bohr model of the atom, as this may still be regarded as the threshold over which the student may later pass into the stately but rather forbidding mansion of quantum and wave mechanics. At the end of the text there is a record, covering fourteen pages, of the most famous names in physics, together with dates and discoveries

Compared with our English textbooks of the same standard, Prof Berliner's book contains remarkably few calculations, although even the Poinsot motions of a rigid body and Coriolis motions are discussed in a descriptive way The emphasis is laid throughout on the physical aspect For teaching purposes the book would gain by the addition of a set of carefully chosen illustrative examples and problems, the absence of which is

rather common in foreign textbooks Prof. Berliner's book may be highly recommended.

(2) Prof Perucca's two volumes on general and experimental physics illustrate again the remarkable improvement that has occurred in recent years in the teaching of elementary physics The standard attained in the present case is about that of an English general degree These volumes represent the substance of a two years course of lectures to students at the Royal College of Engineering at Turin, but they should meet the requirements of pure science students equally well. Italian students are, indeed, fortunate in having so excellent an expositor as Prof Perucca, whose knowledge of every part of the subject is uniformly deep and accurate. The mathematical treatment is always simple, elegant and sufficient Engineers have a particular fondness for neat and clear diagrams. The author has been unusually indulgent in this respect, as the diagrams are in many cases excellent; for example, the *p-v-T* diagram on p 526 of vol 1, or the earlier figures relating to forced oscillations In the second volume special praise must be accorded to the chapter on capacity and dielectrics. The volume ends with short accounts of the photo-electric, photo-voltaic, Compton and Raman effects

The printing and production of the two volumes are of the highest order In view of the many English translations of foreign books on physics that have recently appeared, we may well ponder whether Prof Perucca's work has not an equal claim in this respect for a textbook of this standard.

The Prehistory of Scotland

The Prehistory of Scotland By Prof. V. Gordon Childe. Pp. xv+285+16 plates. (London: Kegan Paul and Co, Ltd, 1935) 15*s*. net.

SINCE Prof Gordon Childe went to Edinburgh, he has made himself master of the ascertained facts regarding Scottish prehistory, and has brought a mind saturated with comparative data to a synthesis such as has not yet been forthcoming in book form In Scotland the main outlines were long ago drawn in by Dr. Joseph Anderson, but since his day a vast amount of information has accumulated, and a great deal has been learned in quite recent times Much remains yet to be done, so that while the body of fact is impressive, conclusions regarding origins and relations must necessarily be provisional. As the author himself writes in his preface, "The data are incomplete, and the conclusions it [the synthesis] offers are provisional or even premature". The conclusions set forth in this volume have authority as coming from one possessed of a wide and varied knowledge of European archæology, and the book will be of value not only to general readers, but also to workers in the field. If it increases general interest in Scottish archæology and stimulates research, it will do a notable service, and will be very welcome

The book opens with a useful and necessary chapter on the geographical and climatic conditions of prehistoric Scotland. It is quite impossible in a short notice such as this to deal in any detail with the vast amount of archæological data contained in the book The meagre evidence for a settlement or settlements of peoples in the epipalæolithic phase is presented, and Azilian, Tardenoisian and Baltic elements are recognised The local Neolithic and early Bronze (in which the author includes the English middle bronze) phase are already fairly fully known, and the current theories of a south-western (Iberian, to use the old term) origin for the people and culture of the chambered tombs, and a Central European origin for the short cist people with their beaker urns, are accepted, discussed and defined in view of recent discoveries Regarding the collective tombs, the author presents a case for the recognition of a type of corbelled tomb in Caithness, apparently belonging to an advanced phase of chamber building, as the earliest importation of the architectural idea from the Iberian peninsula, the segmented chambers of south-western Scotland, of simpler construction, being of later date and rather different origin The effect on the architectural features of the tombs of differences in the building materials available in different districts is pointed out, but perhaps not given quite sufficient weight. For some time now it has been supposed that the Beaker folk settled, not at a single but at a number of points on the east coast, and the author analyses the Beaker pottery from this point of view While he admits the origin of the food vessel from the older neolithic bowl, he suggests as a possibility a settlement of food vessel folk, as an alternative to the entirely local origin of this class of pottery. The evidence from graves makes this more than doubtful.

The bronze age in Scotland lasted for a long period, and the early Iron Age is represented, so far as funerary relics are concerned, by about six graves only. Certain of these indicate some connexion with the graves of the Arras group of chariot graves in Yorkshire, and one can be definitely dated to the first century A D. The culture was then definitely La Tène, and a colonisation from the south has been admitted about this time. The overlap from bronze to iron has been a dark epoch in Scottish archæology. The urn field and Hallstattian cultures of the Continent are only vaguely represented, and the evidences for local

development, influenced of course by trade, are weighty. The author recognises Hallstattian influences in certain of the fictilia of the late bronze age and argues for a definite settlement of people practising the culture on the evidence of sherds of pottery with Hallstatt features in Aberdeenshire, Morayshire, Shetland and some other localities. Owing to the practice of cremation, no anatomical evidence for this is available, and the conclusion must be regarded as tentative

The same must be said of the theory regarding the Broch builders—but this is too large a question to be included in this review All the author's conclusions will stimulate research and discussion, and are welcome on that account

The descriptions throughout the book are not too technical, and are happy in the way they seize on the essential points The maps of distribution, which have involved intensive work, are of much value

Short Notices

De Venarum Ostiolis 1603 of Hieronymus Fabricius of Aquapendente (1533? -1619) Facsimile edition with Introduction, Translation and Notes by Dr K. J Franklin. Pp viii+98+2 plates (Springfield, Ill, and Baltimore, Md. Charles C Thomas; London. Baillière, Tindall and Cox, 1933) 13s 6d

An important early work by Fabricius has now been published by the History of Science Society with the aid of funds contributed by the Carnegie Corporation All English readers who would fully understand the discovery of the circulation of the blood must, after studying the immortal "De motu Cordis", refer to the work of Harvey's precursor and teacher, Fabricius of Aquapendente, "De Venarum Ostiolis", and to that of his successor R Lower, "De Cordo" By his scholarly translations of both of these works, Dr. Franklin has now completed the early trilogy of the circulation—complete in facsimile and translation and with all the original plates Discovery and publication were too often divided by long years The first unintelligent glimpses of valves by Canano 1541, Estienne 1545, Sylvius 1541 and Colombo seem to have been unknown to Fabricius in 1574 when he first made his discovery, and another twenty-nine years elapsed before he published it The salient points in his life are well indicated, and the construction of the anatomy theatre at Padua, where he lectured, is illustrated with architectural plans for the first time The eight fine full-page engravings of the original have been well reproduced, but we regret that the folding plate, pages 10 and 11, was not mounted clear of the stitching R T G

Müller–Pouillets Lehrbuch der Physik Elfte Auflage Herausgegeben von A. Eucken, O. Lummer, E Waetzmann. In 5 Bänden. Band 4. *Elektrizität und Magnetismus.* Teil 3: *Elektrische Eigenschaften und Wirkungen der Elementarteilchen der Materie* Herausgegeben von Arnold Eucken Pp. xviii+828. (Braunschweig: Friedr. Vieweg und Sohn A.-G, 1933.) 54 gold marks.

The present volume of this well-known series of handbooks consists of the following parts: the free electron (cathode rays), by Gerthsen and Kossel; positive rays, passage of electrons through matter, by the same authors; discharges through gases, by Steenbeck; electrical structure of atomic nuclei, by Kirsch and Teller; atomic and molecular forces, by Dunkel and Wolf, dielectric polarisation of atoms and molecules, and pyro- and piezo-electricity, by Wolf The subject matter is treated simply throughout Many useful numerical data are found scattered over the various sections It is a particular merit of the volumes of this series that every effort is made to avoid rendering the reading irksome by inserting unnecessary formulæ or calculations The physical argument is clearly presented and references to original papers are given in abundance in footnotes

Earth, Radio and the Stars By Dr Harlan True Stetson. (Whittlesey House Publication) Pp xvii+336+9 plates (New York and London McGraw-Hill Book Co, Inc, 1934) 10s 6d. net.

There is always a peculiarly individual and peculiarly American quality about the work of Dr Harlan True Stetson, and the present work is difficult to sum up on that account The linkages amongst the rather diverse topics treated are somewhat slender and sometimes artificial, but as topics all are very interesting Variations in longitude and latitude, the internal structure of the earth, sunspots in relation to terrestrial magnetism and radio reception, problems of the ionosphere, solar, lunar and stellar effects on radio transmission, cosmic clouds, cosmic rays, are parts of a science, more attractive than the name 'cosmecology' which the author attaches to it, dealing with the relation of the earth to its cosmic environment The book is often stimulating, sometimes irritating, it contains much that is difficult to find elsewhere, and it should be read

Sound: a Physical Text-Book By Dr. E G Richardson Second edition Pp vii+319. (London. Edward Arnold and Co, 1935) 15s net.

When Dr. Richardson's book first appeared in 1927, it was described in a full review in these columns as "a well-balanced account of the present state of knowledge in experimental acoustics" (Nature, 120, 760; Nov. 26, 1927) Since then, much new work has been done on such subjects as sound-recording, echo-sounding, supersonics, architectural acoustics, limits of audibility, analysis of sounds, and so on, and the book has been expanded from 286 to 319 pages to take these and other advances into consideration. There are new chapters on impedance, supersonics, and the reproduction of sound.

Scientific Investigation of Works of Art

IN the field of the fine arts, it is axiomatic that the history of style cannot be separated from the history of technique and critical study of the latter depends upon two sources of information Of these, documentary evidence is the more obvious and the less readily accessible Some such manuscripts are of classical importance, and have been frequently edited and translated probably the best known are the fifteenth century "Libro dell' Arte" of Cennino Cennini, and the much earlier "Schedula Diversarum Artium" of Theophilus Presbyter, of which first-class translations, critically edited and most copiously annotated, have recently been published Numerous other early and medieval texts dealing with all phases of contemporary craftsmanship have been intensively studied, such as the Lucca "Compositiones" and the fourteenth century "De Arte Illuminandi", while many unpublished sources have yet to receive due attention But comparatively few craftsmen have thus placed on written record their workshop methods . and it can therefore scarcely be too strongly emphasised that detailed analytical study of actual surviving works of art constitutes a second potential source of information of the very highest importance.

Obviously, such sources are much more frequent than purely documentary evidence on the history of medieval craftsmanship and the technique whereby a specific work of art was fashioned, be it painting, bronze, pottery or textile, may often be detected by the trained and discerning eye. It cannot be done in a day Many tricks of medieval craftsmanship are still stubborn secrets and though scientific methods of investigation, applied with reserve and artistic appreciation, have of recent years unravelled a good many such problems, yet the unwritten secret of, for example, the brothers Van Eyck, still continues to be 'discovered' at fairly regular intervals.

The names of a good many pioneer workers are intimately associated with this intensely interesting field where science and the fine arts overlap. It is perhaps invidious to particularise . but Prof Eibner and his collaborators at Munich, and Prof A. P. Laurie in Great Britain, among many other workers, have contributed classical researches to the corpus of available knowledge It should not be forgotten, further, that many museums, galleries, private research workers, and picture-restorers such as Dr. de Wild, have all made use of scientific methods for the examination of works of art But all have admitted the disadvantages inherent in the general absence of a co-ordinating centre of research, though of recent years this deficiency has to some extent been remedied by the excellent work of one or two research departments The laboratory of the Fogg Art Museum, at Harvard University, for example, has systematised many lines of research, and has provided by its quarterly publication, *Technical Studies in the Field of the Fine Arts*, a journal devoted exclusively to disseminating knowledge in this field Further, the invaluable work carried out at the Research Laboratory of the British Museum has led to excellent publications on the constitution and care of museum pieces and works of art of various kinds While paintings have, generally speaking, received little treatment at this latter centre, systematic investigation of such problems, particularly as applied to Russian icons and Byzantine wall-paintings, has been carried out in Moscow at the Institute of Archæological Technology and the Restoration Workshop The results achieved there are not so widely known as they should be, however, largely owing to the language difficulty

The recent establishment, by the University of London, of a Scientific Department at the Courtauld Institute of Art, has focused attention upon this field once more The urgent need for the foundation of a centre where systematic investigation could be carried out into the physical character of works of art, and into the problems connected with their conservation and restoration, was made very clear at a Conference on Ailing Pictures convened by the Department of Scientific and Industrial Research on October 20, 1931 Full tribute was there paid to the work of the British Museum Research Laboratory, and of private investigators . but it was felt that an independent and preferably academic centre would have great advantages over any existing institution, not only in carrying out research, but also in co-ordinating work already being conducted elsewhere The new laboratory marks the fulfilment of the views expressed at this meeting it is now fully equipped, and work is in progress In addition to its research and educational activities, the laboratory is prepared to make scientific investigation into works of art of any type submitted by their owners, both public and private, reporting on their physical constitution and condition, and advising on questions of conservation and restoration

Reports are, however, limited very strictly to matters of scientifically ascertainable fact : questions of attribution to a particular master are not taken up The technique of a Holbein or a Rembrandt cannot yet be expressed as a mathematical function of the materials employed, nor can the *impasto* of a Rubens at present be differentiated

from that of his pupils by any quality or quantity accurately measurable in absolute units

It is significant of the recent increased interest in such problems in Great Britain that the National Gallery has installed specialised equipment for the physical investigation and characterisation of its pictures. and this almost simultaneous establishment of two such research departments in London can scarcely fail to have an important bearing on this field of investigation

The results previously obtained have, perhaps inevitably, given rise to a certain amount of sensational publicity in the Press This is very regrettable. for not only has it led to popular misconceptions, and to the making of extravagant claims for certain scientific weapons, but also it has tended to suggest that all manner of questions, including the thorny problem of attribution, can be settled rapidly and with certainty by scientific means. The publicity accorded to the occasional detection of art forgeries by examination with X-rays, and with ultra-violet and infra-red radiation, has led many a layman to believe that such methods invariably reveal hidden features of deep significance In actual practice, nine out of every ten paintings, on X-ray examination, show nothing of significance—or, at least, nothing which can with certainty be interpreted at the present stage of our experience The outstanding difficulty in investigations of this kind is that of establishing a satisfactory control experiment—a norm for comparison It should never be forgotten that a work of art, of practically any kind, has to be regarded as a 'living' system, in a state of physico-chemical equilibrium which can be radically altered by factors at present almost unknown—as witness the sudden disintegration of certain Italian frescoes, without warning, after centuries of healthy 'life' The independent variables controlling such a system are so numerous that it is doubtful whether any given work of art will ever be defined by a set of specific and reproducible conditions Its very nature is so intensely individual that the cleverest forgery in existence would be an unsatisfactory control for experiment on the original To generalise on a few striking cases is, if possible, even less permissible here than in the exact sciences and significant progress will be obtained only after long-continued experiment under carefully controlled conditions P D R.

Origin of the British Flora

LIKE all other biological phenomena, the British flora is determined by two classes of factors, those of history and constitution on one hand, and those of environment on the other It is obvious that only those species which can at least tolerate the climate of these islands can continue to live here the discussion held at the Royal Society on March 28 was concerned mainly with the problem of how and when they came Light was thrown on this subject by contributions not only from taxonomists and students of the geographical distribution of species, but also from ecologists, meteorologists, geologists and archæologists, though it cannot be said that the problem taken as a whole is very close to solution despite the intensified field-work of recent years We are in fact no farther than the beginning of the laborious collection and analysis of detailed facts which alone can eventually lead to general agreement

Mrs. E. M Reid opened with a paper on "British Floras antecedent to the Great Ice Age" In dealing with the Tertiary floras, she showed that that of the London clay has a large preponderance of tropical, mostly Indo-Malayan forms, which she explained by supposing migration to north-western Europe along the shores of the Tethys Sea—that greatly extended 'Mediterranean' which persisted through so many geological ages. The evidence is that some existing British genera, absent from the London Clay, existed in these regions in earlier times (before the London Clay was laid down) and were presumably driven out by this invasion of tropical climate and flora from the south-east, but the floras of later deposits (subsequent to the London Clay) show a steadily increasing percentage of living British genera, culminating in the late Pliocene with 97 per cent It is generally accepted that the climate and flora of the Cromer Forest bed at the top of the Pliocene were roughly equivalent to those of to-day, and may therefore be taken as the real starting point of the modern flora

Then came the cold of the Pleistocene with the advance of the great continental ice-sheet from Scandinavia and the formation of glacial systems in the mountains of Great Britain It is obvious that these conditions must have exterminated or driven southward most of the existing flora, since the ice advanced at one time to the northern edge of the Thames Valley, and later to South Wales. It is now established, however, that there were four successive glaciations in England—though these do not necessarily correspond at all closely with those of the Continent—and correspondingly three interglacial phases. Prof P G H Boswell, whose work has greatly increased our knowledge of the Pleistocene period in Britain, sketched the

history of these successive glaciations The second reached farthest south in the east (Thames valley), the third and fourth in the west (Bristol Channel) The floras of the interglacial phases when the ice retreated were touched upon by Miss M E J Chandler During the second (middle) interglacial phase, much of our existing flora was present in eastern England, which was at that time joined to the Continent owing to general elevation of the land. Of the others little is known, and there is no evidence that any interglacial was much warmer than the present climate 'Nunataks' (ice-free areas surrounded by ice) no doubt existed during the glaciations, but according to Prof Boswell it is uncertain whether any of these were continuous throughout the Pleistocene, and could thus possibly afford a permanent refuge for Pliocene plants According to Dr Raistrick, there were 50 square miles of such ice-free areas in the Pennines, though none in the Lake District mountains But there is still some difference of opinion on this point The most generally accepted view is that at any rate the great bulk of the existing flora came into Great Britain from the Continent after the final retreat of the ice

The main issue of controversy on the effect of the ice age on the British flora lies in the question whether practically the whole vegetation north of the Thames and Bristol Channel was wiped out, except such as could survive in the comparatively narrow strip south of the ice-sheets, or whether a substantial portion at least survived in ice-free 'sanctuaries', and in the south-west from interglacial or even from Pliocene times In the discussion, Dr A J Wilmott was the protagonist of the latter, Prof E. J. Salisbury of the former view Dr Wilmott's evidence is (1) the occurrence of certain endemic species which are regarded as relics of Pliocene or a warm interglacial period and are very unlikely to have originated in post-glacial times, (2) the aggregations of rare and local species in unglaciated areas south of the ice-sheet such as Brean Down in Somerset and Torquay, or in unglaciated areas surrounded by ice such as Teesdale and Arran. It seemed to him "inconceivable" that such species would have migrated separately to these areas in post-glacial times, avoiding intervening and equally suitable habitats They must rather be regarded as relicts which have survived in these places Prof Salisbury, on the other hand, argued that these collections of rare species have occupied such areas in post-glacial times because the local conditions are particularly suitable for them He does not believe that the cumulative effect of very cold conditions during a glacial phase would permit the survival of such species within the boundaries of or in proximity to an ice-sheet, or that any bounds can be set to the post-glacial migration of species within the British Isles, provided the conditions of existence are suitable for their establishment

The view that relict species surviving the last glaciation may probably be fairly numerous in the British flora was supported by Prof G E. Du Rietz, of Uppsala, who gave many examples of species concentrated and isolated in two mountain areas, one in the north and the other in the south of the Scandinavian peninsula; these can only be interpreted as relict areas, since the nature of the habitat does not in any way explain this localisation of species He also described Norwegian coastal areas which were free of ice during the Pleistocene and possess remarkable collocations of species, and particularly one in Novaya Zemlya in proximity to the existing ice-sheet and known as "flower hill" These instances taken together greatly strengthen the case for survival close to the ice Furthermore, he instanced a species of tropical rain forest lichen still found in south-west Ireland, the presence of which he is only able to interpret as a survival from a pre-glacial tropical climate Prof Du Rietz confessed himself "rather an extreme advocate" of the theory of survival of pre-glacial relicts, believing that a great part of the oceanic (Atlantic) flora survived in the south-west of the British Isles, though he did not oppose Prof Salisbury's contention that the distribution of very many species followed the differentiation of climate, and was thus determined by existing environment rather than by the more remote history of the species Dr W Watson cited several examples of Scottish liverworts and lichens occurring in isolated positions in southern England, both in the west and in Norfolk, interpreting these as glacial relicts

There certainly seems a good deal of evidence derived from the existing distribution of particular species, not only in the British Isles but also on the Continent and in America, for the survival of relicts in particular places, doubtless in more or less specially suitable habitats, from various earlier periods, surrounded by a flora of which they do not form an integral part. But we are still very far from being able to write a convincing history of the extremely complex changes which must have occurred since the Pliocene. Our ignorance of the climates which actually existed in proximity to the ice-sheets is almost complete We cannot assume that all the unglaciated parts of the British Isles must have been arctic tundra The evidence from southern Sweden and Esthonia is that the forest zone there came very close to the ice, and, for all we know, quite mild conditions may have existed in our own south-west, enabling the survival of many 'Atlantic' species, among which

may be reckoned the so-called 'Lusitanian' flora, species which occur in south-western Ireland or in south-west England and also in the Iberian peninsula—some being present in and some absent from western France—among which the strawberry tree (*Arbutus unedo*) is perhaps the best known

Several speakers—for example Miss Chandler, Prof Boswell, Dr W B Wright, Mr Butcher and Dr Hamshaw Thomas—emphasised from different points of view the extreme complexity of the changes and the wide fluctuations of climate and other conditions which must have occurred during the Pleistocene Other speakers, again, directed attention to factors which are probably of great importance but are often ignored—Dr. Thomas to the importance of precipitation and accompanying humidity of the air, in addition to temperature, Dr A S Watt to soil development, different soil phases limiting the spread of particular species and favouring that of others; Dr W. B Turrill to 'ecotypes' within an aggregate species which may all have a general superficial resemblance but in reality differ greatly, both in genetic constitution and in ecological requirements

Dr H Godwin gave a lucid account of the application of the modern technique of pollen analysis to the interpretation of the post-glacial history of the British flora, showing that the succession of forest types in Britain agrees very well in a general way with that recorded from the Continent It is difficult to judge the time of the first appearance of the dominant trees, but the order in which they spread and attained dominance can be determined with some certainty The earliest post-glacial forest phase (Boreal) shows dominance of birch and pine and the entry of elm, oak and lime Later came the alder, and the next climatic period (Atlantic) saw mixed oak-forest and alder dominant It is now certain also that beech, on the native place of which doubts have been cast, was present in pre-Roman (probably Iron Age) times, and hornbeam has a similar status. Both these records agree well with the late post-glacial spread of the two trees on the Continent There is also evidence of a second pine forest maximum between the early Bronze Age and the Roman period, and this perhaps corresponds with the Sub-boreal pine maxima in Ireland, Scandinavia and other parts of Great Britain Not very much is certainly known of the pollen of British interglacial beds, but the presence of spruce—now extinct—has been established, so that extermination of some species at least during the later glaciations appears to be demonstrated

A G TANSLEY

The Alkali Industry

IN the Hurter Memorial Lecture to the Society of Chemical Industry (*Chemistry and Industry*, 54, 121; 1935), Dr J. T. Conroy gave a very interesting review of the development of the manufacture of sulphuric acid, alkali, chlorine and allied products since about 1890. This period has seen the disappearance of the Leblanc process and its replacement by electrolytic processes, the Castner and Hargreaves processes developed in Great Britain having features embodied in most successful modern cells except those of the gravity type. The possibility of operating these processes was almost entirely dependent on power production. The original rocking mercury cell has given way to a trough type with many times the capacity of the original unit, and the use of Acheson artificial graphite for the anodes was a material improvement. The high degree of purity of the caustic soda produced by the Castner cell, fitting it for the electrolytic production of metallic sodium, was very helpful to its development. The sodium is the starting material for the manufacture of cyanide. For the last fifteen years the chlorine produced in Great Britain has been electrolytic in origin.

In the ammonia-soda process, improvement in plant and operation has been effected, and processes for the production of sal ammoniac and calcium chloride from appropriate tower and still liquors have been developed

Although the Leblanc cycle has been superseded, some intermediate products are still important Sulphuric acid is made by the chamber process, in the operation of which some mechanical improvements have been effected, and on the chemical side the use of nitre has been replaced by ammonia oxidation Concentration of acid in platinum pans has given way to other types of apparatus and finally to the contact process It is only with large installations and a demand for high strength acid, such as is necessary in the dyestuffs industry, that the contact process is economical. The use of sulphur has replaced that of pyrites to a large extent since the exploitation of the American deposits by the Frasch process.

The manufacture of saltcake (sodium sulphate) has declined considerably, partly because saltcake is now largely displaced by ammonia soda ash in glass manufacture and partly because the export market demands have been largely met by the recovery of sodium sulphate from residual

liquors from the recovery of natural potash at Kaiseroda and Borbach, from which on refrigeration Glauber's salt is obtained, yielding saltcake of high purity on suitable heat treatment.

The Weldon chlorine process had been displaced by the Deacon process as improved by Hasenclever. The production of 1 ton of bleaching powder by the Weldon process required 50 cwt of salt; in the Deacon process appreciably less than 20 cwt. was used Kynaston found that the undecomposed hydrochloric acid washed from the chlorine was almost free from arsenic and contained but little SO_3, so that this acid could be sold and the costly Hasenclever process, degassing the condensed acid for return to the decomposer, could be avoided A revolution in the manufacture of hydrochloric acid came with the production of synthetic acid from the hydrogen and chlorine gases from the electrolytic cell, and a high proportion of the acid is now produced synthetically.

In the manufacture of bleaching powder, the use of the Hasenclever plant, in which mechanically hydrated lime is pushed through horizontal superimposed cylinders in counter current to the ascending chlorine, has been modified by the omission of the propelling blades and the use of a single enlarged rotating cylinder for the smaller units (Moore and Rudge) The chlorine from the electrolytic cells is diluted with air before use, and by suitable regulation of the process and control of temperature in particular zones of the cylinder by water cooling, a high strength bleaching powder possessed of stability in hot climates can be produced Calcium hypochlorite containing more than 70 per cent available chlorine, and sodium hypochlorite solutions containing up to 15 per cent available chlorine are produced for water purification, sanitation, laundry work and other purposes

The production and sale of liquid chlorine for water purification and the preparation of intermediates in the dyestuffs industry is another notable achievement Chlorate production is now also electrolytic and is carried out in countries such as Sweden and Canada where cheap waterpower is available

In the caustic soda industry, the carbonate from the ammonia soda process is causticised with lime, the calcium carbonate in granular form being removed by rotary filters and used as agricultural lime, in 'stone dusting' in coal mines and, when carefully dried and air-separated, in other industries Regeneration of lime from the lime mud has more recently been accomplished The caustic soda liquor is concentrated in multiple effect evaporators and further in steam-heated units, the product being of high strength, 70 per cent Na_2O being normally attained, whilst with the mercury electrolytic cell a product approximating to 100 per cent NaOH is obtainable New forms of caustic soda known as flake, petal and powder, are made by breaking down thin sheet, they are easy to handle and much purer than the old stick form

Purity of the modern products is due partly to the basic change of process, for example, contact process for sulphuric acid and synthesis of hydrochloric acid, and partly by the possibility of installing purification plant owing to economy resulting from greater output per unit of plant Fuel economy has been largely effected by the development of the tubular boiler and the steam turbine The use of control instruments and better working conditions on the plant, as well as the introduction of metals and alloys capable of resisting corrosive liquids and gases, have all played a part in the improvement of the industry Dr Conroy emphasised that the continuous high efficiency now ruling can only be maintained and ensured by continuous scientific control.

Obituary

PROF. E. PATERNÒ

THE death of Emanuele Paternò removes a leading Italian chemist and a genial collaborator from the international councils of chemistry, where he regularly represented his country Prof Paternò passed away on January 18 in his native city of Palermo, where he was born on December 12, 1847 His father had to leave Sicily soon after his birth, having taken an active part in the revolt of 1848, and Emanuele spent his early years in exile, in Alexandria.

Having graduated in physics and chemistry, Paternò returned to Palermo, replacing in 1872 the famous chemist Cannizzaro, who had just left for Rome. In 1893 he was called to the chair of applied chemistry in Rome, and on the death of Cannizzaro he became director of the Chemical Institute

Paternò's scientific contributions over nearly half a century are numerous and varied. He began his scientific career with the discovery of dichloraldehyde. and made a special study of the halogen isomers of ethane, the synthesis of fluorbenzene, fluortoluene, etc Passing on to physical methods, he made numerous cryoscopic studies in connexion with the determination of molecular weights, and later in life investigated colloidal phenomena and the influence of light upon chemical reactions.

Paternò was the first to point out, in 1889, the emulsion-like nature of colloidal solutions, and to note that a substance may be colloidally dispersed

in one solvent and molecularly dispersed in another In the photo-chemical field he obtained by elegant methods condensations of hydrocarbons with aldehydes and ketones, he succeeded in preparing a number of synthetic alkaloids and was able to throw light on the probable mechanism by which plants produce many of these compounds

In addition to his research activities, Paternò excelled as an organiser He founded and edited the *Gazetta Chimica Italiana* In Palermo he was both principal of the University and mayor of the City, and in Rome he occupied many Government positions A gold medal was founded in 1923 in his honour, to be given every three years for the most notable discovery in chemistry, the first award being made in the same year to Dr F W Aston Prof Paternò was elected an honorary fellow of the Chemical Society in 1920

SIR WILLIAM MORRIS, K C M G , C B

WE regret to record the death of Sir William G Morris on February 26, in North Wales He was a man beloved by all who had the privilege of knowing him Born in 1847, he entered the Corps of Royal Engineers in 1867 After various home duties he went to Mauritius in 1871 and remained there until 1874, the year of the transit of Venus expedition to that island, with which the names of Lord Lindsay and Sir David Gill are so intimately associated This appears to have marked the beginning of that collaboration with Gill which was later to have such useful results in South Africa; for after a spell of two years at the Staff College and later at home duties—particularly as assistant instructor in survey at the School of Military Engineering, Chatham, from 1877 until 1882—he was acting on special duty in 1882–83 under the Transit of Venus Committee at home and abroad

At this juncture, Sir David Gill, who was then H.M. Astronomer at the Cape of Good Hope, had succeeded in persuading the Governments of Cape Colony and Natal to undertake a geodetic survey of their territories. To carry out this work Gill naturally turned to Morris, who after two months work on special duty under the Colonial Office, became the leader of the Geodetic Survey of the two Colonies, an undertaking which absorbed his energies for ten years Officially he was noted for special duty under the Government of Natal, which was the first of the two Colonies to support Gill's proposal for the geodetic survey. This work, indissolubly associated with the names of Gill and Morris, was the beginning of the Great Arc of the 30th Meridian which last year was carried to the Belgian frontier of the two provinces of Ruanda and Urundi

On his return home, Morris received the C M G for his services on the geodetic survey of the Cape and Natal. He next went to Chatham and in the period 1895–98 was assistant commandant of the School of Military Engineering, but South Africa was calling, and he returned there in 1898 as Colonel on the Staff, C.R.E., acting as district engineer during the South African War (1899–1902). He was twice mentioned in dispatches and received various honours and the C B After the war an occupation doubtless more congenial to his nature was in store for him in 1902 he became officially superintendent of the Geodetic Survey of the new territories, and in 1906 completed the principal triangulation of the Orange River Colony (as it then was) and the Transvaal He retired from the Army on half pay in 1904 and for the last thirty of his long spell of eighty-eight years lived very quietly on a mountain side overlooking Bettws-y-Coed Visiting him there about three years ago, the present writer found that his mind had apparently drifted beyond South Africa, the scene of his former triumphs

Gill and Morris built up in South Africa a fine school of geodesy Supported by able assistants, they established a tradition which has not been without effect on the world at large Mr Victor A Lowinger, one of these assistants, writes "Morris was devoted to his work and inspired all who worked under him with the value of thoroughness and accuracy He chose his men carefully and trusted them to get on with the job, while at the same time he was always ready to resolve any difficulties that arose He was of a very reserved nature and, though a little intolerant of human weaknesses, very just in his judgments—a man with whom one has been proud to have been associated in one of his great practical contributions to geodesy" G T M.

MR M V PORTMAN

WE regret to record the death of Mr Maurice Vidal Portman, which occurred at Axbridge, Somerset, on February 14, at the age of seventy four years. Mr Portman was well known as an authority on the natives of the Andaman Islands as they existed fifty years ago He was appointed "Officer in charge of the Andamanese", with headquarters at Port Blair, in 1879, and remained in the Andamans until 1899, when he was sent home on account of ill-health Throughout his term of duty he was in constant and intimate touch with the life of those tribes of shy, difficult and sometimes dangerous, little people As a result of his care for them and his disregard for the risks he ran in getting into touch with them, he acquired knowledge of their customs and beliefs which made him the equal, if not indeed the superior, as an authority, of E H Man, although the latter won the wider reputation through his books Mr Portman was a contributor of papers on Andamanese matters to the publications of learned and scientific societies, and made a remarkable collection of photographs of the Andamanese and their articles of material culture

WE regret to announce the following deaths.

Sir John Rose Bradford, K C.M G , C.B., C B.E , F.R.S , emeritus professor of medicine in University College, London, president of the Royal College of Physicians in 1926–31, on April 7, aged seventy-one years

Prof. E. Cannan, emeritus professor of political economy in the University of London, on April 8, aged seventy-four years

News and Views

Planning in Industry

PLANNING in industry was debated in the House of Commons on April 3, following a motion by Mr A H. E Molson calling for the establishment of a Departmental Committee to consider the measures of industrial reorganisation necessary for the fullest use of modern methods of production and distribution in Great Britain Mr Molson urged the necessity for dealing with the industrial position of the country as a whole and not by Departments of State or the like singly, and referred particularly to the reduction of costs of production and the question of cheap distribution Organisation of industry on a national basis was regarded by Mr C U Peat as essential, both for the older and the newer industries, thus organised self-government would have avoided the present desperate redundancy problem in the canning industry. The essence of the proposal was that the majority of an industry should have the opportunity of putting their case before an independent tribunal, and on satisfying the tribunal that re-organisation was in the interests of producers, consumers, wage-earners and other allied industries, statutory authority should be given to the reorganisation scheme without delay, so that the industry should be organised on the most efficient basis it could suggest Mr H Macmillan said further that the question was not one of Government interference with industry but the giving by Government of certain rights to industry by permissive legislation to undertake its own reorganisation Under certain safeguards, majorities should have the right to govern

DURING the debate, Mr G Le M Mander advocated the establishment of a committee of national development to formulate a consistent and comprehensive policy for the development of our national resources and to co-ordinate the work of different Departments of State Sir Herbert Samuel, referring to the dangers of bureaucracy, emphasised the importance of management The ablest leaders of industry, he said, are themselves in favour of larger measures of reorganisation for the industries in which they are engaged The opposite point of view was voiced by Mr. R. Assheton in a brilliant plea for independence and the adventurous spirit in industry on which progress primarily depends, and which is liable to be stifled by rigid organisation. The dangers of eliminating small enterprises were real and Mr. Assheton feared the effect of planning on business confidence. Mr. W. Runciman, for the Government, emphasised the success of voluntary schemes of industrial reorganisation and referred to some of the failures in rationalisation. He expressed the opinion that the reorganisation of all the great industries of Great Britain cannot be achieved by one and the same effort. The motion was by leave withdrawn

Development of Colonial Forest Resources

THE Secretary of State for the Colonies has set up an organisation under the Colonial Office for the development of colonial forest resources By consent of the Department of Scientific and Industrial Research, two of its technical officers have been transferred to the new organisation, namely, Major F M Oliphant, lately assistant director of the Forest Products Research Laboratory, Princes Risborough, and Major J R Cosgrove, lately in charge of the Section of Utilisation at the Laboratory. Major Oliphant, as forest economist, will deal mainly with the organisation of production, and will spend much of his time in the Dependencies concerned, while Major Cosgrove, as market development officer, will be engaged in market promotion work, with reference to the United Kingdom market and other markets, both British and foreign The organisation will be chiefly concerned with timber development, but will also interest itself in other forest products, such as wood pulp, fibres, gums and resins and the like In both directions it will co-operate with the Imperial Institute It will also work, of course, in close co-operation with the Forest Products Research Laboratory The Laboratory, as a research institution, will henceforward confine itself to questions involving scientific investigation and tests, while the new organisation will take over the market promotion work, including commercial service trials, which the Laboratory formerly carried out under temporary arrangements on behalf of the Empire Marketing Board The organisation will for the present be quartered at the Imperial Institute Inquiries should be addressed to the Colonial Forest Resources Development Department, Imperial Institute, London, S W 7

Statistics of Industry in England and Wales

STATISTICS of industry derived from the 1931 census of England and Wales have recently been published (London : H M Stationery Office, 32s. 6d), and as the analysis is on a more comprehensive scale than any hitherto published, the volume is of exceptional interest A valuable feature is the rough comparison with previous censuses, examples of which are given in the following table

Industry	1911	1921	1931
	Persons (in thousands)		
Coal Mining	971	1,133	1,030
Iron and Steel	166	239	198
Building, Decorating	861	758	1,048
Agriculture	1,230	1,124	1,018
Cotton	628	596	571
Electrical Apparatus, etc	80	166	268
Chemicals, Paints, Oils	133	198	211
Hosiery	59	80	110

In certain industries, for example, coal mining, iron and steel, engineering and shipbuilding, exceptional expansion took place during the War, but this was followed by a considerable readjustment during the last decennium. In others, for example, building, personal service, boots and shoes, there was a marked decline, but recovery followed after the War. The numbers engaged in agriculture, cotton and lace have declined in each census since 1911, though in poultry

farming there has been an increase from 12,200 persons in 1921 to 27,700 in 1931 The manufacture of electrical apparatus, chemicals, paints and oils; hosiery, food, printing and bookbinding, road transport, and a number of other industries have expanded considerably in both census periods since 1911 An interesting fact recorded in the latest census is a great increase in the number of male commercial travellers, from 81,347 in 1921 to 120,212 in 1931

Economic Study of Japan's Population Problems

"CONFLICT and Co-operation, Economic and Political, in the Pacific" formed the theme of the Cawthron Lecture, 1934, delivered by Mr. Frank Milner, at Nelson, New Zealand (Nelson, N Z · Cawthron Institute, 1934) There are, he said, ominous explosive potentialities in Japan's growing population pressure with its increase of more than one million per annum Her population density is now 437 persons to the square mile, and though this is exceeded by Java, Belgium, England and Holland, the situation is complicated by the fact that only 16 per cent of the land is arable With 2,774 persons living on each square mile of such land—not a foot of land being wasted—Japan has reached the point of complete saturation Half the farms are less than 1¼ acres in extent and three-quarters less than 2½ acres. The Japanese are not an emigrating people, and there are only about 635,000 living abroad The only feasible solution of the basic population problem of Japan is the development of manufacture and trade, though inadequate resources of coal, iron ore, petroleum and other raw materials handicap her industrial expansion. Moreover, Manchuria, according to scientific experts, cannot provide coal or iron ore of the type needed for Japanese blast-furnaces The shift from an agricultural to an industrial economy is far from complete, and at present less than 10 per cent of the population work in factories employing more than five persons Japan to-day is the real problem of the Pacific, and her isolation is breeding an ugly mood in her militarists The solution may involve regional allocation of raw materials and markets to Japan involving heavy sacrifices, but such co-operative effort must be made if a cataclysm is to be avoided

François Emmanuel Fodéré

THE centenary of the death of François Emmanuel Fodéré, who was born on January 8, 1764, is to be celebrated on April 12 at Strasbourg, where he was professor of medical jurisprudence from 1814 until 1834. His "Traité de médecine légale et d'hygiène publique ou de police sanitaire", of which the first edition was published in 1798 and the second in 1813, was the standard work in medical jurisprudence in France during the early part of the last century. In 1819 he was appointed lecturer in the history of epidemic diseases and hygiene at Strasbourg, his lectures being afterwards published in four volumes in 1822–24. His other works included "Traité du goître et du crétinisme, précédé d'un discours sur l'influence de l'air humide sur l'entendement humain" (1790), "Essai historique et moral sur la pauvreté des nations, la population, la mendicité, les hôpitaux et les enfants trouvés" (1825), "Recherches sur la nature, les causes et le traitement du Choléra-morbus" (1831) and "Essai sur les diverses espèces de folie" (1832)

Moses Maimonides

THE January issue of *Medical Life* is a Maimonides number containing an account by Prof Louis Gershenfeld, of the Philadelphia College of Pharmacy and Science, of the Hispano-Jewish physician, astronomer and theologian, Moses Maimonides or Abu Amran Musa Ben Maimon, on the occasion of the octocentenary of his birth Born at Cordova in Spain on March 30, 1135, he studied under Averrhoes, and in 1160 left Spain for Fez, finally settling in 1165 at Cairo, where he died on December 13, 1204. His best-known medical work is a collection of 1,500 aphorisms from Galen's writings with forty-two critical comments His other chief medical works are a treatise on diet and personal hygiene written at the request of Saladin's eldest son, who suffered from melancholia, and a book on poisons and antidotes In a work on astronomy, he recognised the limitations of astrology, and declared that all works on the subject were the products of fools He differentiated between astrology and astronomy, maintaining that in the latter only was to be found true and necessary knowledge His most famous work, however, was the "Guide for the Perplexed", which was not intended for popular consumption, but claimed to be written by a philosopher to the philosophically minded, his purpose being to reconcile Aristotelian philosophy with Jewish theology and the doctrines of Judaism

Water with Heavy Oxygen

THERE has recently been erected in the Chemistry Department of the University of Manchester an apparatus of the type first described by Hertz (*Z Phys*, 79, 108, 1932) and afterwards modified by Harmsen (*Z Phys*, 82, 589, 1933) for the separation of gaseous isotopes by diffusion The immediate object is to prepare oxygen containing an excess over the normal of the O^{18} isotope For this purpose it is convenient to diffuse water vapour rather than oxygen itself The abundance of H_2O^{18} is approximately 1 . 500 and the ratio of the vapour densities of the 'heavy' and 'normal' water is 10 · 9 The apparatus was designed to yield water containing about one per cent of H_2O^{18} The process of separation is very much slower with water vapour than with permanent gases owing to the adsorption of the vapour on the walls of the porous tubes used for the diffusion This adsorption is large even at 100° C A trial run just completed has yielded about 20 mgm of water the density of which is greater than normal by about 25 parts per million, which is scarcely if at all outside the experimental error of the density measurement. The apparatus is now being modified somewhat to allow of faster working, and it is hoped that it will yield about 20 mgm a day of water

containing 0·5 to 1 per cent of H_2O^{18}. The water so obtained (or the oxygen prepared from it) will be used as an 'isotopic indicator' in reactions involving oxygen. A specimen of such water prepared by Hertz has already been used to investigate the mechanism of saponification of esters (Polanyi and Szabo *Trans Faraday Soc*, 30, 508, 1934)

The Naturalist in the Laboratory

SIR FREDERICK GOWLAND HOPKINS delivered the Bacot Memorial Lecture entitled "The Naturalist in the Laboratory" before the London Natural History Society on April 2. Sir Frederick pointed out that early biology was limited to study of the physiology and morphology of plants and animals (chiefly vertebrates), the causes which affected them being largely conjectural, the chemist provided means of elucidating these problems Observation of the bombardier beetle and its explosive excretion first attracted Sir Frederick's notice to these matters fifty seven years ago, and despite this first experiment proving fruitless, it was this which led to his taking up biochemistry. The work of the biochemist in comparing the action of catalysis with enzymes has established the processes at work which enable both plant and animal to digest and transform food materials into substances suitable for oxidation to enable life to continue But it does not stop there, for it has shown the relationship between species by the parallel processes carried on in similar species, and that each species may have its own process A further stage has been to show the necessity for certain substances to allow the full utilisation of food supplies Known as vitamins, they provide the means for the body to obtain enough fuel to supply full growth and reduce vulnerability to disease Although systematic, taxonomic, morphological and physiological research must continue, and the biochemist can still open new avenues for exploration, there is every scope for wide co-operation between all branches of natural history from an ecological point of view Finally, although exact chemical reactions in plant and animal can be ascertained and reproduced experimentally, and although living tissues can be made to function under artificial conditions, the origin and nature of life is a matter which scientific research has yet to explain

A New Wind Tunnel

THE new 24-ft wind tunnel at the Royal Aircraft Establishment, Farnborough, opened by the Secretary of State for Air on April 5, is the largest in Great Britain. It can contain a complete aeroplane, all of the machine except the outer portions of the wings being in the air stream and under observation. Air speeds equivalent to 115 miles per hour are obtained The principal immediate use of this type of tunnel is the investigation of 'interference' between various bodies in juxtaposition, such as airscrews and engine cowlings, which cannot be studied precisely upon small-scale models. Such problems cannot be examined as fully as is necessary in actual flight owing to the uncertainty of the steadiness of the air at the moment of taking an observation, and moreover, such experimental flying with new and untried design ideas involves considerable risk, and often delay, in bad weather This tunnel is not the largest in the world, there being a 60 ft × 30 ft one at Langley Field, United States, and a 50 ft span one in France (see NATURE, Feb 16, 1935, p 252) It is interesting to note that one of the first machines to be investigated in this channel will be a new one that has exceeded its anticipated performance in certain respects by so much as to shake confidence in the accepted methods of estimating the total air resistance of combinations of differently shaped bodies

Shortt Clock at the Science Museum

A SHORTT free pendulum clock has recently been installed at the Science Museum, South Kensington, and is now at work controlling the main public dials of the Museum The Shortt clock was perfected by Mr W H Shortt in 1921 as a result of a long period of experimental work in association with Mr F. Hope-Jones and the Synchronome Company, the first clock was set up at the Edinburgh Royal Observatory in 1921, and Prof R A Sampson's report on its first year's run aroused great interest among astronomers, as it had proved to have surpassed all previous clocks in its accuracy A Shortt clock was adopted as the sidereal standard at Greenwich at the beginning of 1925, and has proved itself capable of measuring time to an accuracy of a few thousandths of a second per day, or better than 1 in 10^7 The clock now exhibited in the Science Museum is identical with these observatory clocks except that the usual exhausted copper case for the free pendulum is replaced by a dust tight glass cylinder the clock is mounted on the wall of a public gallery with its slave clock by its side The delicate method of imparting an impulse to the free pendulum and the action of the hit-and miss synchroniser can thus be studied in detail

Excavations at Jericho, 1934–35

DURING the season which has just closed, Sir Charles Marston's archæological expedition to Jericho, of which Prof John Garstang is field director, has penetrated to the neolithic levels of earliest occupation which, it is found, cover a considerable portion of the site, under deposits of the Early Bronze Age measuring 27 ft thick. In the neolithic levels, forming a layer 18 ft deep, were found sealed deposits in the form of a series of superimposed house structures, in which the floors had been plastered, coloured red, and burnished There is evidence to show that the walls of these structures had been treated in a similar fashion. One of the most interesting finds, according to a dispatch reporting the results of the excavation in *The Times* of April 4, is the head of a cult image of human form made of unbaked clay, in which the eyes are represented by shells. It was found in association with sherds of Thessalian painted pottery and fragments of primitive local ware immediately below the Early Bronze Age levels. The flint

industry of the neolithic levels is of the characteristic Palestinian type Although Palestine is not likely to rival Iraq in the number and intrinsic value of its archæological finds, the sense of its importance grows as further exploration brings to light cumulative evidence of the part it played as a meeting place of cultural influences from a diversity of directions

Portrait of Owen at the Natural History Museum

THE Trustees of the British Museum have received by the bequest of Mr Cyril B Holman-Hunt, who died last year, the portrait of Sir Richard Owen, which was painted in 1881 by his father, the well known artist, William Holman-Hunt, O M It has been hung on the east pier near the main entrance in the Central Hall of the Natural History Museum The picture was in the possession of the artist's daughter, Mrs Joseph, but she readily acceded to her brother's wishes as expressed in his will, and arranged for its transference from the Athenæum, where it was temporarily on loan In the picture, Owen is depicted in Hunter's gown seated in an armchair The position in the Central Hall is far from suited to a glazed picture, but it is the best at present available in the building, the trustees have, however, undertaken to provide one more satisfactory whenever the public part of the Museum is extended It is fitting that the portrait should find a place at South Kensington, because Owen was superintendent of the Natural History Departments of the British Museum from 1856 until 1884 He had therefore a great say in the planning of the new building and the allocation of space in it to the several departments, and was in control when the building was opened to the public, on April 18, 1881 Incorrectly but justifiably, he is usually known as the first director of the Museum. In addition to the distinction of the subject, the picture has considerable interest as a work of art, because the eminent artist seldom engaged in portraiture, and only about five examples of that side of his work are known

British Empire Cancer Campaign

AT the fifty-fourth meeting of the Grand Council of the British Empire Cancer Campaign held on April 10, it was announced that a grant at the rate of £350 a year for the year 1935 has been made to Sir Leonard Hill for the services of Dr T Reiter whilst continuing his research work on short wave therapy in the laboratories of the St. John Clinic and Institute of Physical Medicine On the recommendation of the Physical Sub-Committee of the Scientific Advisory Committee, a grant of £1,000 a year for two years has been made to the North of England Council of the Campaign, to be placed at the disposal of Prof. W E. Curtis, of the Armstrong College, Newcastle, and Dr. F Dickens, research director of the Cancer Research Institute of the North of England Council, for the purpose of conducting an exhaustive scheme of research in short wave therapy. A grant of £700 has been placed at the disposal of the Scientific Advisory Committee for a special investigation, under its supervision, of the biological reactions of monochromatic radiations of various wave-lengths The Grand Council has decided to continue to offer from time to time a prize and medal for the best essay submitted on a set subject concerning cancer research, gold medals will also be awarded from time to time to those in the British Empire who have carried out and published contributions to cancer research of outstanding merit

New Mount Everest Expedition

THE Mount Everest Committee announces that another Mount Everest Expedition will take place during 1935 36, with the consent of the Tibetan Government Mr Hugh Ruttledge, who led the 1933 expedition, has been offered, and has accepted, the leadership The Committee, the chairman of which is Sir Percy Cox, will in due time make an announcement of plans The first Mount Everest expedition under Col H Bury was in 1921 This was followed by a second expedition under General C G Bruce in 1922, and a third under Lieut -Colonel E F Norton in 1924 On that expedition, Mr G A Leigh-Mallory and Mr A C Irvine lost their lives in the last thousand feet of the ascent, but it is not improbable that they reached the summit The fourth expedition, in 1933, met with exceptionally bad weather conditions and was forced to abandon the attempt when success seemed to be within sight In 1933, the Houston Mount Everest expedition made a flight over the summit and secured photographs

Field Trials of Agricultural Crops

FURTHER reports of the field trials carried out in Great Britain under the auspices of the National Institute of Agricultural Botany have been published in its *Journal* (vol 3, No 3 2s 6d) As before, stress is laid on the necessity for carrying out the experiments at several centres simultaneously, and for repeating them for three consecutive years, before really reliable recommendations can be made The results of the trials of cereals in Essex (1927–29) are now complete 'Yeoman' and 'Yeoman II' proved by far the best of the winter wheats, and all autumn sown varieties were on an average £3 per acre more valuable than those sown in the spring As regards barley, 'Plumage Archer' was the most generally grown, although 'Spratt Archer' gave quite as satisfactory yields. Autumn sowing if successful was profitable, a gain of £2 per acre being obtained, but the risk of bad winter conditions has, of course, to be taken into account 'Grey Winter' proved the hardiest and best yielder of the winter oats grown, but both standing and yielding capacity were lower than desired Spring oats generally gave a higher yield than winter varieties. In every case the advisability of early sowing is emphasised, not later than the middle of November for autumn sowing, and during February for the spring varieties. The growing of named, rather than unknown, varieties is also of the first importance, as it may mean a difference of as much as £3–£4 per acre in the value of the return Results from potato and sugar beet trials are also given, and

the publication concludes with the fourteenth annual report of the Official Seed Testing Station for England and Wales.

Humane Slaughter

IN the thirteenth annual Benjamin Ward Richardson Lecture which was delivered before the Model Abattoir Society on November 27 and has just been published, Sir Leonard Hill, who had chosen for his subject "Electric Methods of Producing Humane Slaughter", maintained that Richardson's aim for humane slaughter was fulfilled by the introduction of the electric stunning instrument, which was a safe process and free from the objections made against shooting. The current is obtained from the usual 200 volt 50 cycle A C lighting current, and is reduced to 50 volts by a transformer The electrodes, which are at the ends of the jaws of a tong like instrument, are applied for 5 seconds in the case of pigs and for 20 seconds in the case of cattle, after soaking in 20 per cent saline, one on each side of the jaw of pigs, and between the eyes and ears of calves and sheep The old method of electrocution, which caused violent contractions and even rupture of and hæmorrhage into the muscles, is avoided by this process, and no spilling of blood occurs

Geographical Methods and Earth Stucture

THE Pontifical Academy of Sciences of the Vatican City announces the offer of a prize of 10,000 lire, to be awarded for an original, unpublished thesis dealing with the utilisation of geophysical methods in the investigation of the interior of the earth Scientific men of all nationalities are invited to submit theses, five typewritten copies of which, in French, Italian or Latin, should reach the Academy before November 1 of this year No ordinary member of the Academy, whether resident in Rome or elsewhere, is eligible to compete The name of an author may be appended to his thesis or, alternatively, the authorship may be indicated by a motto or sign In the latter event, the name of the author should be enclosed in an envelope marked outside with the motto or sign A special committee, nominated by the Academy, will judge the theses submitted, and the award will be presented to the successful author at the first meeting of the next session of the Academy, to be held in December

Fifty Years of Chemical Theory

THE Liversidge Research Lecture delivered before the Australian and New Zealand Association for the Advancement of Science in January by Sir D Orme Masson dealt with "Crucial Advances in Chemical Theory during the last Half-Century". The lecture gave a brief summary of the initiation of the theory of solution and electrolytic dissociation, the discovery of the inactive elements, X-rays, radioactivity, atomic numbers and the nuclear theory of the atom, isotopes, positive rays and a generalised formula for the structure of all atoms proposed by the lecturer in 1921. The latter states that, if p is a proton, e an electron, N the atomic number and A the true integral mass of the atom, with n (necessarily integral) equal to the difference $A - 2N$, then every neutral atom may be represented by the formula $[(p_2e)_N\ (pe)_n]e_N$, in which the nucleus is enclosed in the square bracket and the external electronic system is outside it In the case of hydrogen, $n = -1$ The groups pe and p_2e have since been discovered in the neutron and the heavy hydrogen nucleus, respectively

The Ray Society

AT the annual general meeting of the Ray Society on March 20, the following officers were re-elected *President*, Sir Sidney Harmer , *Treasurer*, Sir David Prain ; *Secretary*, Dr W T. Calman Prof F. E Weiss was elected a vice-president, and Mr R Adkin, Dr. Stanley Kemp, and Mr E A. Robins were elected new members of Council. In the report of the Council it is announced that the second and final volume of Prof Stephenson's work on British sea anemones is about to be issued, and it is stated that the publication of this finely illustrated and costly work has been rendered possible by contributions from the Government Grant Fund of the Royal Society, and from several private donors, among whom Mr J Spedan Lewis is specially mentioned It is announced that the issue to subscribers for the current year will be the first volume of a work on British Neuroptera by Mr. F. J. Killington.

Thunderstorm Survey

MR S MORRIS BOWER, of Langley Terrace, Oakes, Huddersfield, informs us that the annual survey of thunderstorms in the British Isles which he has instituted will be continued during the coming summer Mr. Bower will be glad to receive details as to the place, date and time of the occurrence of thunder, lightning or hail Records of damage by lightning will also be especially welcome. The space and time distribution maps of thunder have recently thrown useful light on the question of storm travel, and on its association with meteorological and geographical considerations. The areas of greatest damage by lightning are not necessarily those of maximum storminess, and in view of the value of the determination of such areas in electric power transmission, it is proposed to pay particular attention to this aspect of the survey.

Benefaction for Research into Short-wave Therapy

THE Medical Research Council has agreed to act as trustee in administering a benefaction of £4,000 provided by the Stock Exchange Dramatic and Operatic Society and named in honour of the secretary of the Society, Mr. Hugh S. Quekett. The purpose of the gift is the promotion of research into the value of short-wave radiation in the treatment of disease. The money will be used by the Council to meet the cost of assistance and special apparatus in experimental and clinical investigations to be made at the London Hospital under the direction of Prof. D. T. Harris, Dr. E May, and Sir Robert Stanton Woods.

First Shipment of Petrol from Billingham

PENDING the completion of the erection of the plant for the direct hydrogenation of coal, the first

shipment of petrol, some 300,000 gallons, produced by the hydrogenation of creosote at the Billingham plant of Imperial Chemical Industries Ltd, has been loaded into the s.s. *Otterhound*, at Billingham. The petrol is being delivered to the Shell-Mex-B.P. Company which, with the Anglo-American Company, are undertaking distribution on behalf of the producers. This delivery initiates regular traffic between Billingham and east coast ports of Great Britain.

Announcements

PROF. F. G. DONNAN, professor of general chemistry in the University of London, has been elected an honorary member of the Chemical Society of Rumania. Prof. Donnan has also been invited by the Danish Natural Science Association to give three lectures in Copenhagen during the week beginning May 20.

HIS MAJESTY THE KING has approved the award of the Royal Medals of the Royal Geographical Society as follows: Founder's Medal to Major R. A. Bagnold, for his journeys in the Libyan Desert; Patron's Medal to Mr. W. Rickmer Rickmers, for his long-continued travels in the Caucasus and Russian Turkistan culminating in his leadership of the Alai-Pamir Russo-German Expedition of 1928. The Council has awarded the Victoria Medal to Mr. E. J. Wayland, for his work on the Quaternary geology of Uganda and the Rift, and its relation to man.

THE Gold Medal of the Institution of Mining and Metallurgy has been awarded to Mr. Alfred Chester Beatty, in recognition of his distinguished services to the mining industry in the development of mineral deposits, with particular reference to the copper resources of Northern Rhodesia. The following awards have also been made: the Consolidated Gold Fields of South Africa Ltd. Gold Medal to Dr. David Williams, for his geological researches and for his paper on "The Geology of the Rio Tinto Mines, Spain"; the Consolidated Gold Fields of South Africa Ltd. Premium of forty guineas to Mr. William Henry Wilson, for his paper on "The Tri-dimensional Projection of Mine Workings"; the Arthur Claudet Students Prize of ten guineas to Mr. Charles Patrick McMillan, for his paper on "Milling Methods and Costs at the Alaska Mine Flotation Plant of the Southern Rhodesia Base Metals Corporation, Limited, Southern Rhodesia"; the William Frecheville Students Prize of ten guineas to Mr. James G. Traill, for his paper on "The Relation between Width and Cost in Narrow Stopes".

MR. B. H. ST. JOHN O'NEIL has been appointed inspector of ancient monuments for Wales. He has been assistant inspector of ancient monuments for Wales since 1930.

THE following have been elected officers of the Royal Aeronautical Society for 1935–36: *President*, Lieut.-Colonel J. T. C. Moore-Brabazon; *Vice-President*, Mr. H. E. Wimperis; *New Members of Council*, Major T. M. Barlow, Major G. P. Bulman, Dr. H. Roxbee Cox, Prof. G. T. R. Hill, Dr. N. A. V. Piercy; *Honorary Treasurer*, Major D. H. Kennedy; *Honorary Librarian*, Mr. J. E. Hodgson.

THE following appointments have recently been made by the Secretary of State for the Colonies: Mr. F. C. Jessop, to be adviser in animal husbandry, Department of Agriculture, Malta; Mr. J. B. Polding, to be veterinary pathologist, Malta; Mr. R. N. Twisleton-Wykeham Fiennes, to be veterinary officer, Uganda; Mr. H. C. King (late assistant conservator of forests, Ceylon), to be assistant conservator of forests, Mauritius; Mr. F. B. Wade (senior assistant geologist), to be Government geologist, Department of Lands and Mines, Tanganyika; Mr. E. B. L. Colborne, to be engineering chemist, Public Works Department, Gold Coast.

IT is probable that the Challenger Society will be making further grants in aid of research during the year 1935–36. The General Committee is prepared to consider applications for small grants in aid of research in marine biology at a recognised laboratory during the current year. Applications, accompanied by details of the proposed research, should reach the Honorary Secretary, Mr. J. R. Norman, British Museum (Natural History), S.W.7, before the end of April.

THE original autograph manuscript of Alcide d'Orbigny's celebrated work "Foraminifères" which formed part of Ramon de la Sagra's "Histoire Physique, Politique et Naturelle de l'Île de Cuba" (Paris, 1839), has been acquired for, and added to, the Heron-Allen Library of Foraminiferal Research at the British Museum (Natural History).

PROF. A. Wolf's work on the beginnings of modern science and technology will be published shortly by Messrs. Allen and Unwin, Ltd., under the title "A History of Science, Technology and Philosophy in the Sixteenth and Seventeenth Centuries". The book is a comprehensive account of one of the most interesting scientific periods in the world's history, and is profusely illustrated from old prints.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—Engineers for the Building Research Station, Garston, and two junior scientific officers at the Road Research Laboratory, Harmondsworth—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (April 17). A teacher of mechanical engineering in the Ipswich School of Engineering—The Secretary for Education, Tower House, Ipswich (April 18). A lecturer in zoology in the University of Capetown—The Secretary to the High Commissioner for the Union of South Africa, Trafalgar Square, London, W.C.2 (April 30). An assistant lecturer in mechanical engineering in the University of Sheffield—The Registrar (May 3). An analyst and demonstrator at the Harper Adams Agricultural College, Newport, Shropshire—The Principal. A director of pathology and Lyle research scholar at Queen Mary's Hospital for the East End, Stratford, E.15—The Secretary.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 587

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Radiopotassium and other Artificial Radio-elements

IN a letter published in NATURE of January 19, it was shown that the bombardment of scandium with neutrons leads, beside the formation of an active scandium isotope[1] $_{21}Sc^{46}$, to the formation of a new potassium isotope $_{19}K^{42}$ having a half life value of about 16 hours and emitting β rays the intensity of which is reduced to one half of its initial value by an aluminium foil of approximately 0 7 mm thickness We were recently successful in preparing this potassium isotope K^{42} by the bombardment of calcium by neutrons according to the equation

$$_{20}Ca^{42} + {}_0n^1 = {}_{19}K^{42} + {}_1H^1$$

Calcium carbonate, after being exposed to neutrons produced by a mixture of 200 300 mgm radium emanation and beryllium powder, was dissolved in dilute hydrochloric acid, 150 mgm sodium chloride added and the calcium precipitated as oxalate The filtrate was found to be active and the measurement of both the rate of decay and the absorption of the radiation emitted has shown the presence of $_{19}K^{42}$ The yield of K^{42} from calcium is a low one, which is due chiefly to the fact that the isotope Ca^{42} is only present to the extent of 0 8 per cent in the mixed element calcium It is now possible to produce the potassium isotope K^{42} by each of the following reactions

$$\begin{aligned} &(1)^2 \quad {}_{19}K^{41} + {}_0n^1 = {}_{19}K^{42}, \\ &(2) \quad {}_{20}Ca^{42} + {}_0n^1 = {}_{19}K^{42} + {}_1H^1, \\ &(3) \quad {}_{21}Sc^{45} + {}_0n^1 = {}_{19}K^{42} + {}_2\alpha^4. \end{aligned}$$

When applying neutrons slowed down by Fermi's device by reflection by hydrogen nuclei, an active calcium isotope was obtained which decays with a period of 4 hours, the formation of which is due to one of the following two reactions,

$$\begin{aligned} {}_{20}Ca^{40} + {}_0n^1 &= {}_{20}Ca^{41}, \\ {}_{20}Ca^{44} + {}_0n^1 &= {}_{20}Ca^{45}; \end{aligned}$$

the latter being the more probable one

We investigated also the action of neutrons the velocity of which was reduced by the use of paraffin, on zirconium and hafnium, and found that the active zirconium obtained decays with a period of 40 hours, the intensity of the β-rays emitted being reduced to one half of its initial value by an aluminium foil of 0 5 mm thickness The disintegration of the active hafnium is much slower than that of zirconium, half of the activity acquired being lost only after the lapse of a few months Radio-zirconium is presumably formed according to the equation

$$_{40}Zr^{96} + {}_0n^1 = {}_{40}Zr^{97}$$

In the case of hafnium, every place between the mass numbers 176 and 180 being occupied by a known stable isotope, the formation of the active hafnium isotope can only be due to the process

$$_{72}Hf^{180} + {}_0n^1 = {}_{72}Hf^{181}$$

On emitting β-rays, according to the equation,

$$_{72}Hf^{181} = {}_{73}Ta^{181} + \beta,$$

the active hafnium isotope becomes the only stable isotope of tantalum known

Extension of the Ultra-Violet Wave-Length Limit

THE best light source for the spectroscopy of the extreme ultra-violet region is the hot spark In the spectroscopic work at this Institute, the electrodes of the spark are usually connected through short straight leads to four condensers having a capacity C of 0 4 μF together These are charged to a tension V = 50–70 kv. The discharge through the spark is periodic with a period T of about 8 μ sec (corresponding to a wave-length of 2,400 metres) The maximum current in the spark is

$$i_{max} = V\sqrt{\frac{C}{L}} = 2\pi\,\frac{CV}{T}$$

If in our case, V = 50 kv, we have i_{max} = 16,000 amp If we wish to increase the current in the spark we have to increase the tension V, which is possible only to a certain extent Further, we can increase the capacity C, but this gives a rather slow increase in i Finally, we can decrease the inductance in the circuit

FIG 1 Spectrum of spark between carbon electrodes Time of exposure ½ hour Focused at about 30 A.

Now the straight leads from the condensers to the spark do not give the minimum inductance. In fact, if we 'cable' the leads so that the current flows in the interior of a cable in one direction and returns

on the outside of the cable, the resulting inductance decreases considerably.

We have connected each of the four 0 1 μF condensers through three cables to the electrodes of the spark This diminishes the resulting inductance to almost 0·1, so that the period decreases to one third and the maximum current increases three times. At 50 kv we then have $i_{max} \sim 47{,}000$ amp (if the discharge is still periodic)

We have investigated the spectroscopic effect of this increase in the spark current with the help of a concave grating spectrograph having the plate at right angles to the Rowland circle[1] The grating had a radius of 1,800 mm and was ruled at this institute with 288 lines a millimetre The angle of incidence was 1 65°

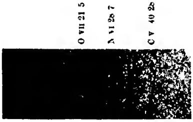

FIG 2 Spectrum of spark between carbon and carbon + lithium nitrate electrodes Time of exposure 2½ hours Focused at about 20 A

With the condensers connected in the usual way, we have obtained with graphite electrodes the C V-line at 40 A rather well The C V line at 34 A and the C VI-line (the first line of the Lyman series) at 33 A were faint but visible after half an hour's exposure

When the condensers were 'cabled', the intensity of these lines increased very much, especially the C VI-line Moreover, the second Lyman line of C VI at 28 A was detected

When some lithium nitrate was placed in one of the carbon electrodes, the first N VI-line at 28 A and the first O VII-line at 21 A. became visible after about 1 hour With aluminium electrodes, some Al XI-lines down to 38 A appeared

Thus the short wave limit of the ultra-violet has been extended from 33 A [2] down to 21 A

Magnetic Properties and Critical Currents of Supra-conducting Alloys

IN previous papers[1] we reported that, in the stable state of supra-conducting lead, the induction B is always zero. We shall now discuss measurements carried out with a lead–thallium alloy corresponding in composition to $PbTl_2$ and an alloy of 65 per cent lead and 35 per cent bismuth. The measurements were made at various temperatures with the method we have previously described (method No. 2)[2].

In Fig. 1 is shown the relation between induction B and field-strength H for $PbTl_2$ at $T = 2 \cdot 11°$ K The experiments show that

(1) Up to a definite critical field-strength H_{k_1}, which depends on the temperature, B remains nearly zero In this region the behaviour of alloys and pure metals is the same

(2) In the field interval from H_{k_1} to H_{k_2}, the induction increases with the field strength, gradually approaching the value characteristic for the non-supra-conducting metal Electrical measurements carried out on wires from the same melt showed that the potential difference remains equal to zero right up to the field strength H_{k_2} In the field interval from 0 to H_{k_2} the induction is independent of time

(3) At the second critical field-strength H_{k_2}, which is 1700 gauss at $T = 2 \cdot 11°$, the alloy loses its supra conductivity The magnetic properties undergo no change at this point

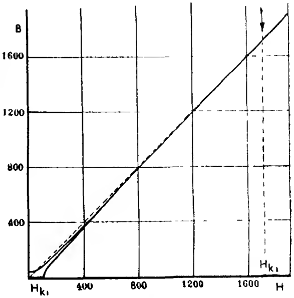

FIG 1

(4) When the field-strength is then decreased, a slight hysteresis is observed and at zero field-strength a small residual magnetisation remains, which does not depend on time

The critical temperature was determined by measuring the electrical conductivity and the magnetic properties, and was found in both cases to be 3 75° K At all temperatures below T_0 the relation between B and H corresponds to Fig. 1 Above T_0 the magnetic permeability is unity, which denotes that there are no nuclei of free lead in the alloy

The experiments with the Pb–Bi alloy gave qualitatively similar results

We have already published measurements on the specific heat of the lead–bismuth alloy[3] showing that no appreciable jump in the specific heat was observed at T_0 Thus the specific heat and the magnetic measurements are not in agreement with Gorter's theory[4].

Finally, we can report on some measurements of the critical electric current in the $PbTl_2$ alloy which destroys supra-conductivity Wires of this alloy 0·71, 0·33 and 0·26 mm in diameter were prepared The appearance of a resistance was observed as the current was gradually increased. The experiment

was performed at various temperatures. We found that supra-conductivity is destroyed when the magnetic field at the surface of the wire reaches a definite critical value The critical field-strength caused by the current is slightly less than H_{k1}

Thermal Rotations of Fluorescent Molecules and Duration of Luminescence

IMPROVED fluorometer measurements, to be published elsewhere in detail, of the duration of luminescence τ of dye molecules yielded an unexpected result, in that τ for fluoresceine in water or ethyl alcohol solution was found to be apparently greater than that in glycerine solution. This is contrary to theoretical expectations, according to which τ should be approximately proportional to the fluorescence efficiency, and it is known that this is rather greater for glycerin than for water solutions

It seems, however, that the effect of thermal rotations of the dye molecules can account for this effect The rotations of the molecules excited, for example, by polarised light, tend as is well known to equalise the values of all intensity components This accelerates the decay of the intensity component I_1 parallel to the incident light vibrations and prolongs it for the perpendicular component I_2 As a result of this, there is an increase of the degree of depolarisation from its value ρ_0 for non-rotating molecules to $\rho > \rho_0$ On the basis of F Perrin's theory of polarised fluorescence[1], we have been able to deduce the following formulæ for the time of decay of I_1 and I_2.

$$I_1 = \frac{I_0}{3}\left[1+2\rho_0+2(1-\rho_0)\exp\left(-\frac{3(\rho-\rho_0)}{\tau(1-\rho)(1+2\rho_0)}t\right)\right]\cdot\exp\left(-\frac{t}{\tau}\right) \qquad (1)$$

$$I_2 = \frac{I_0}{3}\left[1+2\rho_0-(1-\rho_0)\exp\left(-\frac{3(\rho-\rho_0)}{\tau(1-\rho)(1+2\rho_0)}t\right)\right]\cdot\exp\left(-\frac{t}{\tau}\right) \qquad (2)$$

where I_0 is the value of I_1 for $t = 0$. The full argument will appear elsewhere

From equations (1) and (2), it appears that the rates of decay are not exponential, but that they are a sum or a difference of two exponential functions. Only for $\rho = 1$ or $\rho = \rho_0$ are they exponential and corresponding to the mean life period of the excited molecules In all other cases, for $\rho_0 < \rho < 1$, I_1 decays faster and I_2 slower than $e^{-t/\tau}$. As mentioned above, experiments have shown that for I_1 the observed time of decay τ_{obs} of fluoresceine in glycerine solution is smaller by about 20 per cent than that for a water solution where $\rho = 1$ For I_2, however, the difference between the τ_{obs} for water and glycerine solutions is within experimental errors, which were about 5 per cent.

Fig 1 shows τ_{obs} for I_1 and I_2 for fluoresceine as a function of ρ in different glycerine – water mixtures

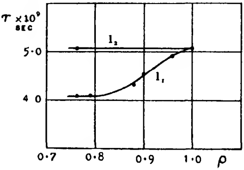

FIG 1

Although for I_2 the differences between τ_{obs} for water and glycerine solutions are within the limits of experimental error and therefore cannot be at present detected experimentally, it seems that the hypothesis put forward above can give at least a qualitative explanation of the phenomena observed

Polymerisation of Formaldehyde

EXPERIMENTS on the autoxidation of gaseous formaldehyde (at 100° C) in the light of the mercury arc showed the existence of a rapid induced polymerisation, which continued unabated as a dark reaction on switching off the light No oxidation occurred during this 'dark reaction'.

The cause was traced to the formation of formic acid in the illumination period It was then found that the addition of small amounts of formic acid vapour to pure formaldehyde gas precipitated a rapid and complete polymerisation of the latter, the rate of which was uninfluenced by light. The pressure – time curves showing the progress of the polymerisation with varying concentrations of added formic acid are compared in Fig 1. Whereas, even at so high an initial pressure of formaldehyde as 500 mm. of mercury, the thermal polymerisation normally proceeded only at a rate of about 16 mm per hour, when 34 mm. of formic acid was present, the pressure fell at an initial rate equivalent to 2,295 mm. per hour—some 140 times as fast.

The apparatus used for these experiments contained a stopcock and a ground joint connecting the quartz reaction vessel to the glass portion of the system (which was electrically heated). Neither of these could be directly heated, and it was observed that the solid polymer separated mainly at the cold part. Experiments performed in a completely heated glass system, however, confirmed the observations made in the first apparatus—except that in this case there was a residual pressure, due probably to the presence of a gaseous polymer, and the solid polymer separated out on the hot wall.

The order of the reaction is approximately unimolecular over most of the range, and the rate is not appreciably affected by packing the vessel with

quartz tubes. The formic acid does not appear to be used up appreciably during the reaction, titration showing that practically as much remained at the end as was introduced initially

Detailed considerations of these experiments have led us to the view that the polymerisation of formaldehyde, induced by formic acid, proceeds by a chain mechanism, in which the starting of reaction chains and also the branching are controlled kinetically by the formic acid

The results suggest that it is probable that the stability of monomeric formaldehyde depends mainly upon its freedom from traces of formic acid vapour.

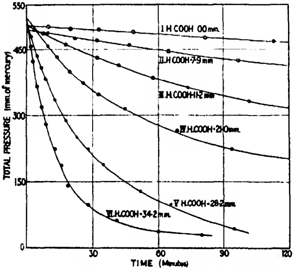

FIG 1 Polymerisation of formaldehyde catalysed by formic acid

We have found, further, that acetic acid is efficient as a polymerising agent, while preliminary experiments with acetaldehyde vapour at room temperature show that a similar polymerisation may be induced by formic acid. In this case the pure aldehyde appeared to be perfectly stable, but addition of 25 3 mm. of formic acid vapour to 298·2 mm. of acetaldehyde caused the pressure to fall at an initial rate of about 2 mm. per minute, and brought about a total diminution of pressure amounting to 162·7 mm. of mercury

Concentration and Ionising Tendency of Carboxylic Acid Groups in Cellulose and other Natural Products

CELLULOSE which has been subjected to oxidation with an alkaline oxidant is presumed to contain carboxylic acid groups, but does not show acid characteristics of the order usually associated with this group. The reason for this is that, whilst the carboxylic acid groups are ionised *within the cellulose phase*, the hydrions are unable to escape into external water, since the anions form part of the cellulose lattice.

A theoretical consideration of the ionic equilibria in the system 'oxycellulose' – dyestuff – water led to the expectation that the constraint on the movement of the hydrions would be overcome by the addition of a neutral electrolyte Indeed, if the Donnan theory of membrane equilibrium is applicable, in presence of excess sodium chloride, the concentration of sodion, and therefore that of hydrion, in the external solution should become equal to the respective concentrations within the fibre

A qualitative experiment showed in a striking manner the existence of this effect. A sample of 'oxycellulose', washed until the washings were neutral, was placed in water and methyl red (pH 4 2–6 3) added The colour changed slowly towards a final pH of 5, on account of interchange between the indicator sodions (present in very low concentrations) and the carboxylic acid hydrions When sodium chloride was added a very marked further change took place Acid 'streamed' out the fabric and in a few seconds the colour indicated a pH below 4

In the presence of excess sodium chloride, 'oxycellulose' becomes sufficiently acid to be titrated directly with sodium hydroxide, using an indicator turning slightly on the acid side of the neutral point A ready method of determining the content of carboxylic acid groups is thus provided Moreover, by the determination of the change of pH with salt concentration, it should be possible to evaluate the ionisation constant of the carboxylic acid groups

A New Type of Anomodont Reptile

IT is almost a hundred years since the first Anomodont reptile was discovered in South Africa by Andrew Geddes Bain This skull was sent to Owen and in 1844 he described it under the name *Dicynodon lacerticeps* Numerous other *Dicynodon* skulls were afterwards sent to London and are now in the British Museum (Natural History) The typical *Dicynodon* is very mammal-like in much of its structure, but is remarkable in having had a horny beak something like that of the tortoise, with in addition in the male a powerful permanently growing tusk in each maxilla and no other teeth

During the latter half of the nineteenth century many species of *Dicynodon* were described, and a number of other genera more or less allied to it, and in the last thirty years our knowledge has increased so greatly that we now know about 130 species of *Dicynodon* and its allies These are grouped in an order called the *Anomodontia* Some have tusks in both sexes · some have no tusks in either sex Some have a row or a number of rows of molar teeth. But all agree in that the premaxillaries are fused to form a beak, and hitherto no species has been known in which there are any teeth in the premaxillaries.

A couple of months ago I discovered in beds of the *Endothiodon* zone of the Karroo an imperfect little skull, which on being developed reveals a new type of palate in that there is a number of teeth on the premaxillaries. In many respects the skull resembles that of some of the small Endothiodonts, such as *Cryptocynodon* of Seeley, or *Prodicynodon* or *Emydurunus*; but the presence of at least seven teeth on each premaxilla separates it markedly from all previously known *Anomodonts*. These teeth are not like incisors, growing from the front of the

bone, but are fixed in the back of the fused premaxillaries as shown in Fig 1.

This new type of Anomodont I propose to name *Eumantellia mirus*, after Gideon A Mantell, one of the greatest of our early palæontologists, and chiefly remembered by his discovery of *Iguanodon*

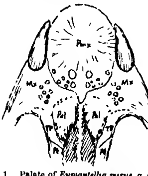

FIG 1 Palate of *Eumantellia mirus*, g et sp nov Natural size

Though *Eumantellia* is too late in time to have been the ancestor of the Dicynodonts and the Endothiodonts, it must be morphologically very near to the common ancestor The loss of the premaxillary teeth would result in a primitive Endothiodont such as *Prodicynodon*, and the further loss of the molars would result in a primitive Dicynodont Possibly we may yet discover an earlier type with an unspecialised premaxillary, and incisor teeth in front

It is manifest that *Eumantellia* must be placed in the Anomodontia, but it seems necessary to make it the type of a new family Eumantellidæ

Retinoscopy of *Loris*

IN connexion with a study on the affinities of the lorisiform Primates, I have had the opportunity, through the kindness of Prof F O'B Ellison, of the Physiology Department of this College, of examining the retina of the living Slender loris with the aid of a Gullstrand large simplified ophthalmoscope.

An adult female animal was placed under very slight ether anæsthesia, sufficient to enable the head to be manipulated freely into the desired position Two drops of 1 in 10,000 atropin solution were placed in one eye This dilated the pupil fully in a few minutes, the other pupil remaining contracted in its normal slit-like condition The instrument was easily focused on the retina and the animal did not move the eyeball about unduly during the examination

The retina gave a very brilliant reddish golden reflex with minute scintillating spots due to the presence of a tapetal layer. This masked the detail somewhat, but was overcome by the use of a green filter. The optic disc consisted of a very darkly pigmented central area, surrounded by a paler ring and then by a marginal zone of lighter pigment From the disc emanated six large vessels and some smaller delicate ones There were three temporal vessels, upper, middle and lower, and likewise three on the nasal side A fair-sized vessel corresponding in position to a macular artery arose from the disc between the middle and lower temporal vessels This artery passed transversely outwards and divided into two branches, the upper of which crossed over a branch of the middle temporal vessel and then returned again No spot where the retina was differentiated to form a macula could be seen This does not preclude the possibility, however, that on microscopic examination of sections a primordium maculæ such as has been described by Woollard[1] in *Tarsius* may not be found

There are in the peripheral parts of the retina of *Loris* a number of small transversely running vessels One of these at least appeared to be an anastomotic channel between the lower temporal and the lower nasal vessels The central artery of the retina in *Loris* therefore is not an end-artery in the anatomical sense.

Cystine and Protein Relationship of Grasses

AN interesting relationship between the cystine content and the protein content of grasses collected through different periods of the year has been established A coefficient of correlation of + 0 923 for 10 pairs, indicating an almost perfect relationship between the protein content and the cystine content of the grasses throughout the year, is demonstrated The accompanying curves (Fig. 1) show a marked fall in both the protein and cystine contents of the grasses through the winter months, with a corresponding rise of both during the commencement of the rainy season during September and October As would be expected, the rainfall curve shows a fair correlation between protein and cystine contents

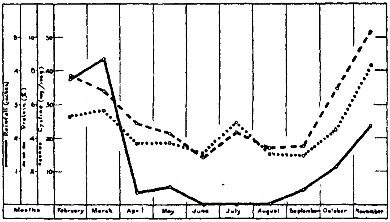

FIG. 1

The grasses were collected at random during ten successive months from the University of Pretoria farm in 1932. The protein analyses were carried out by Mr. F. N. Bonsma at the University of Pretoria and the cystine analyses were undertaken at this

laboratory. The method for the latter was based on a modification of the cuprous-mercaptide precipitation described by Rossouw and Wilken-Jorden in the *Biochemical Journal*. All material was dried at 103° C.

Interaction of Radio Waves

PRIOR to the observation of the interaction of radio waves[1], the study of the propagation of such waves through the atmosphere was concerned only with the effect of the ionosphere on them. The converse effect, namely, the influence of electric waves on the ionosphere, has already been considered by us in a theory of radio interaction[2].

One of the stated consequences of our theory is that the modulation M, impressed by the interfering wave on the wanted wave, is proportional to $1/\sqrt{(f^2+780^2)}$, where $f/2\pi$ is the modulation frequency of the interfering wave; that is, the impressed modulation should be distorted in favour of the lower frequencies.

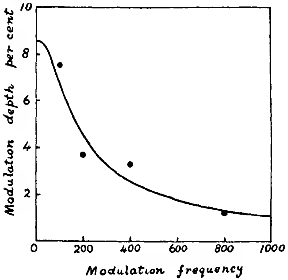

FIG. 1.

There were in Australia no stations sufficiently powerful to allow us to verify this prediction, but its truth has been since confirmed by many observers in Europe, notably Drs. B. van der Pol and J. van der Mark[3] and several members of the World Radio Research League.

The quantitative observations of Drs. van der Pol and van der Mark give strong support to our theory, as may be seen in the accompanying diagram (Fig. 1) where the black dots represent the observed values of the 'depth of modulation' with different modulation frequencies, and the smooth curve represents the formula $y = 670/\sqrt{(f^2+780^2)}$.

The number 780 which occurs in the denominator is the product of two factors, G and ν, the values of which were derived by us respectively from the investigations of Townsend and Tizard on the motions of electrons in air and from the estimates made by Appleton and Chapman of the collision frequency ν in the Heaviside layer. Thus the observations of van der Pol and van der Mark are consistent with the conclusions of the above-mentioned investigators.

Frequency of Collision of Electrons in the Ionosphere

WE were much interested in a recent communication[1] in which Mr. T. L. Eckersley described the way in which he had measured the collisional frequency of electrons in the F_1 region of the ionosphere by comparing the absorption coefficients and group retardations of returned echoes. It is a well-known fact that the effects of the F_1 region are only evident during the hours of daylight, and this presumably accounts for the fact that Mr. Eckersley's observations were made between 1550 and 1630 hr., that is, about one hour before sunset.

Recent experiments have led us to the conclusion that waves reflected from the F region are appreciably absorbed in the E region during the day, and that this E region absorption decreases rapidly near sunset. This view is not in agreement with that of Mr. Eckersley, who considers[2] that F region echoes are not appreciably absorbed in the E region. In accordance with our view, therefore, we do not consider that Mr. Eckersley is justified in neglecting the decrease of E region absorption during the course of his experiment, and it is our opinion that experiments of this kind should only be done at times when either (i) there is no absorption in the E region, that is, at night, or (ii) when the E region absorption is not changing with time, that is, about 1400 hr., the time of maximum E region absorption.

Working with these points in mind, we have been using a method of the same kind as that described by Mr. Eckersley to investigate the F_2 region, but we have restricted our observations to the two times mentioned above (for the F_2 region observations are possible at all times of day or night). In October of last year we found the average value of the collisional frequency to be $1 \cdot 6 \times 10^3$ per electron per second.

Linkage of Chemical Changes in Muscle

WE should like to report some experiments which form an extension of those recently described by Parnas[1], and his colleagues. These workers, using muscle *brei* poisoned with iodoacetic acid, found that synthesis of creatine phosphate could go on, provided that phosphoglyceric acid was added to the *brei*. Breakdown of phosphoglyceric acid can only

proceed if adenylic acid or adenylpyrophosphate is present, and the synthesis of creatine phosphate was only observed during the short interval of time before the complete deamination of the co-enzyme in the iodoacetic acid *brei*.

Our experiments were carried out with dialysed muscle extracts, which have the advantage of containing no carbohydrate or carbohydrate breakdown products, so that the addition of poison is unnecessary in showing the phosphoglyceric acid effect. When phosphoglyceric acid (0·14 mgm. phosphorus per c.c. extract mixture), adenylic acid and creatine were added to such an extract of frog muscle (buffered at pH 7·2 with bicarbonate and phosphate), after 1 hour at 18° C., about 20 per cent of the phosphoglyceric acid phosphorus had appeared as creatine phosphate phosphorus, and about 60 per cent as inorganic phosphorus. Controls showed that no creatine phosphate and no increase in inorganic phosphate appeared in the absence of adenylic acid, whether or not creatine was present. Creatine cannot therefore dephosphorylate phosphoglyceric acid without the help of the adenylic compounds.

Results similar in most respects were obtained with rabbit muscle extract, which showed greater activity. Changes in pyrophosphate content were also estimated here. After 1 hour at 18° C., of 0·14 mgm. phosphoglyceric acid phosphorus added per c.c. of the extract mixture, 80 per cent had disappeared, 20 per cent appearing as phosphagen phosphorus, 25 per cent as adenylpyrophosphate phosphorus, and 20 per cent as inorganic phosphorus. In an experiment with a lower concentration of adenylic acid, as much as 44 per cent appeared as phosphagen phosphorus. Even after 2 hours standing at 37° C. and 6 hours dialysis at 0° C., addition of phosphoglyceric acid and creatine to the rabbit extract gave a small phosphagen synthesis, and breakdown of about 50 per cent of the phosphoglyceric acid. It is likely that this effect is due, not to the dispensability of adenylic acid, but to the extreme difficulty of removing it completely from rabbit muscle extract.

None of the extracts showed any phosphagen synthesis when adenylic acid and creatine were added and phosphoglyceric acid omitted. In all cases, when phosphoglyceric acid phosphorus disappeared, the formation of pyruvic acid was observed.

The theoretical implications of these results have been discussed by Prof. Parnas. We ourselves incline at present to the view that reaction first takes place between adenylic acid and phosphopyruvic acid (formed as an intermediate between phosphoglyceric acid and pyruvic acid), and that the resulting adenylpyrophosphate then reacts with creatine (reverse Lohmann reaction), but further work is needed here. Adenylpyrophosphate apparently not only reacts with creatine, but also breaks down into adenylic acid and *free* phosphate, so that exhaustion of the phosphoglyceric acid supply would lead ultimately to the disappearance of adenylpyrophosphate, and of creatine phosphate also by Lohmann's reaction with adenylic acid.

We are indebted to Prof. O. Meyerhof for the specimen of phosphoglyceric acid used.

Interpretation of Fermat's Principle

IN order to demonstrate the possibility that an optical path between two fixed points may be merely stationary, that is, neither maximum nor minimum, Mr. T. Smith[1] includes in the infinite number of paths with which an actual path is to be compared those which in one homogeneous medium are non-rectilinear. Thus in Fig. 1, if A' is the image of A due to the lens PQ, the actual path $APA'B$ is compared with the longer and shorter imaginary paths $APCB$ and $AQDB$.

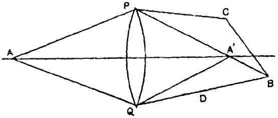

FIG. 1.

Fermat's Principle, stated in the form "The optical path of a ray from one fixed point to another is stationary", excludes from consideration all rays such as PCB which in one homogeneous medium are non-rectilinear. Hamilton[2], more than a century ago, demonstrated rigorously that "the property of *stationary length* belongs (in free space) to straight lines and to such only". Presumably, it is neglect of this fact which leads Mr. Smith to state "It is clearly a trivial matter to demonstrate that no given optical path is ever a maximum". The usual demonstrations of the possibility of maximum paths on reflection or refraction by consideration of aplanatic surfaces[3] are not, as Mr. Smith suggests, erroneous.

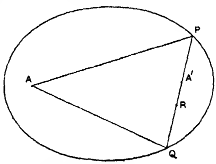

FIG. 2.

Mr. Smith states that the time happens to be a minimum when the path does not include an image of an end-point of the range considered, but if the path includes such an image, the time is neither a maximum nor a minimum—it is simply stationary. To this generalisation several objections may be raised. In the first place it is clear that, even if correct, it would apply only to reflection or refraction by aplanatic systems. Secondly, if in his Fig. 1, B is on the axis, his method of argument would not serve to show that the path $AA'B$ is simply stationary. Thirdly, the statement is not true in the case of reflection by an elliptical mirror of light from a point source at a focus. The path APR (Fig. 2) contains the image A' but it is not simply stationary, it is the maximum, and AQR is the minimum, of all paths from A via the mirror to R.

The application of Fermat's Principle to paths through non-aplanatic systems generally involves a lengthy mathematical procedure A relatively simple case is that in which the end-points are on the axis of a refracting sphere. When the end-points are equidistant from the sphere, the actual non-axial paths are merely stationary while the corresponding axial paths are minima.

O DARBYSHIRE

Physics Department,
Armstrong College,
Newcastle-on-Tyne.

[1] NATURE, 133, 830, 1934
[2] *Dublin Univ Review*, p 795, Oct 1833 Mathematical Papers, 1, 311, 1931
[3] Drude, "Theory of Optics", 9-11, 1902

IN the wave theory of light, the 'geometrical' laws of optics—rectilinear propagation, reflection and refraction—and other results besides, rest on a single principle. The fundamental postulate is that any train of waves may be replaced by a sheet of sources of suitable intensities and phases, that is, paths such as APCB of Fig 1 of Mr Darbyshire's letter are to be taken into consideration equally with paths like AQDB Of all possible paths, the 'rays' of geometrical optics are found to be stationary paths and so suitable for phase calculations; this is the essence of Fermat's Principle.

Of the specific objections Mr Darbyshire raises the first rests on an unnecessary restriction of 'image' By this term we ought to understand any point where the wave system exhibits a singularity, this normally corresponds to the re-intersection of any two neighbouring rays arising from the same object point As regards the second, I have *assumed* the stationary property throughout, and the reasoning used is, I think, generally applicable with a symmetrical system As to the third objection, which has been mentioned by other physicists also, it may be observed that, according to geometrical optics, APR and AQR are the only possible paths between A and R for a single reflection, and the labelling of two isolated paths as a minimum and a maximum seems to me inappropriate in any case Taking the more general view of the wave-theory, the mistake to which I directed attention is due to the neglect of the Jacobi test[1] for the existence of maxima and minima The need for this test can be formally shown by considering the lengths AP and PR of Fig 2, which, as Mr Darbyshire mentions, are the minimum paths from P to A and R The statement that the path APR is a maximum then takes the form

$$\text{minimum} + \text{minimum} = \text{maximum},$$

which is obviously false

Points from Foregoing Letters

RADIOPOTASSIUM (atomic mass 42) has been made from potassium atoms of mass 41 and from scandium atoms of mass 45 by bombarding them with neutrons It has now been obtained by Prof G Hevesy and Miss Hilde Levi, in the same manner, from calcium atoms of mass 42 These investigators have also prepared radioactive isotopes of calcium, zirconium and hafnium from the corresponding elements

Prof. H. Alfvén and Mr. V. H Sanner have obtained ultra-violet light of very short wave-lengths (down to 21A, on the borderland of X-rays) from a spark discharge between graphite electrodes

The relation between the intensity of the field applied and the magnetic induction produced in lead-thallium and lead-bismuth alloys at very low temperatures (when their electrical resistance approaches zero) is described by Messrs. J. N. Rjabinin and L. W. Shubnikow. They show that above a certain field strength the alloys lose their 'supraconductivity'.

Contrary to theoretical expectations, the duration of luminescence of fluoresceine in water and in alcohol was found to be greater than in glycerine. Dr. A Jabłoński and Mr. W. Szymanowski consider that this unexpected behaviour can be explained by the rotation of the molecules

Mr. J. E. Carruthers and Dr. R. G. W. Norrish report that the presence of a small amount of formic or acetic acid quickens the condensation of gaseous formaldehyde to its solid polymer (known commercially as 'meta') They act in a similar way upon acetaldehyde vapour

Mr. S. M. Neale finds that the addition of salt to oxicellulose liberates its acidic hydrogen ion. The action can be made use of in the quantitative estimation of the acidity of oxycellulose.

The anomodont or dicynodont reptiles differ from all the other mammal-like reptiles, in having no teeth in the premaxillary bones The discovery of a fossil type which has teeth in the premaxillaries is reported by Prof R Broom It helps to bridge the gap between the several known families of reptiles.

Mr. S D. Rossouw finds a close proportionality between the percentage of cystine and of protein in grass in South Africa throughout the year The sulphur compound, cystine, is a constituent of sheep's wool.

Messrs F T Farmer and J A Ratcliffe have determined the average frequency of collisions between electrons and molecules in the F_2 region of the ionosphere (about 300 km high) Their experiments were carried out at times of the day when the absorption of the reflected waves by the E region (about 100 km high) does not change with time, a precaution which, they state, Mr Eckersley did not take when he measured the collisional frequency of electrons in the F_1 region (about 200 km high).

Working with dialysed muscle extracts, Dr D M Needham and Mr W E van Heyningen confirm the findings of Prof Parnas and his co-workers that adenylic acid and creatine are essential intermediaries in the reaction by which the muscle obtains its energy from the transformation of glycogen into lactic acid

Mr O. Darbyshire criticises the illustrations given by Mr T Smith, who has claimed that Fermat's principle requires an optical path to be stationary only, and not necessarily a maximum or a minimum Mr. T. Smith, in replying, justifies his consideration of non-linear optical paths in his variational treatment, by reference to the extended Huygens' principle.

Research Items

Archæological Studies of Disease Introduction. The archæologist has always to press into his services the methods of other sciences, and Dr John H Provinse, assistant professor of archæology at the University of Arizona, according to a communication issued by Science Service of Washington, D C, is utilising recent botanical studies in an interesting manner to check data upon the occurrence of disease among American Indians in prehistoric times Dr A E Douglass, astronomer of the University of Arizona, has developed very thoroughly the use of annual rings to determine dates over a period running back through many centuries, the western American climate having led to the formation, over wide regions, of growth rings that appear well correlated with varying climatic conditions Dr Provinse now attempts to match the growth rings in fragments of woods buried with diseased Indians with this well-established 'tree-ring calendar' The tree-ring calendar has enabled the age to be determined of many pueblos and cliff dwellings, and Dr Provinse now hopes to determine how far back various diseases that affect the skeleton can be traced Among the diseases diagnosed in these early Indians are Pott's disease, rickets, osteomalacia, a nutrition disorder of adult women resembling rickets, arthritis and Paget's disease The origin of syphilis is in the minds of the workers, but its diagnosis on pathological bone characters appears uncertain It is stated that so far there is no proof that it existed in America before the coming of Europeans

Cultural History of Cook Inlet, Alaska. Dr Frederica de Laguna's report on her expedition to Cook Inlet (University of Pennsylvania Museum, Philadelphia, 1934) covers the material collected during three seasons (1930-32) spent in Cook Inlet and Prince William Sound The main objective of the expedition was to investigate the question whether an earlier population with an Eskimo culture had preceded the present Athabascan Indians. The evidence considered here is based mainly, though not exclusively, on material from Kachemak Bay The Kachemak culture is interpreted as falling into four stages The basis seems to have been a fairly generalised type of Eskimo culture which included a number of elements common to the Arctic and North Pacific areas The stone industry of the earlier times is characterised by the relatively greater importance of chipping, including even the chipping of slate. Later, polished slate grows in importance and chipped stone becomes less important In the second period notched stones appear in great abundance. In the bone industry, the importance of Thule Type 1 is to be noted in the First Period Pottery and copper are rare and are restricted to the last phase of the Third Period The Second and Third Periods alike have flexed burial with grave goods. The dismembered burial is peculiar to the Third Period Artificial eyes and clay masks are characteristic of the Third Period Scattered and broken human bones belong to all periods except the First The house of the Second Period is partially built of stone and whalebone, that of the Third Period is entirely of wood Both are semi-subterranean The Eskimo dog, fairly well represented in the First Period, declines in numbers throughout the development of the culture. The culture of the First Period has more points of resemblance to the Arctic Thule culture of Canada, while that of the Third Period, which is the best known in this investigation, shows development away from the more typical Eskimo pattern towards a more specialised local complex

Education of Exceptional Children. In Pamphlet No. 49 of a series on "Teachers' Problems with Exceptional Children", published by the U S A. Education Office, Miss Elisa Martens deals with the children who, though not up to the normal standard of intelligence, are yet able to profit by training at an ordinary school Here they grow up in a normal environment, and can be trained for useful citizenship It is essential that the teacher should be interested in these children, and should study each case individually The curriculum should be modified for them if necessary, and their physical fitness promoted by care and by training in health habits, but above all they must be made happy, and this can best be done by giving opportunities for the expression of such talents as they possess in creative activity. Mentally retarded children need the same basic types of educational activities as do normal children, but the teaching should be as practical as possible The pamphlet gives much practical advice on a subject which must concern all those who are in any way responsible for the young

Preventive Inoculation against Diphtheria. In the spring issue of the *Fight against Disease* (**23**, No 1), the journal of the Research Defence Society, Sir Leonard Rogers contributes an article on the effect of preventive inoculation on the incidence and severity of diphtheria in nurses and children. He concludes from an analysis of a large mass of statistics that the Schick testing for susceptibility and the preventive inoculation are quite harmless, and no serious or harmful effect, still less a fatality, has resulted among 150,000 individuals treated Of 15,478 'protected' children, only 0 1 per cent were attacked, but no less than 22 5 per cent of 258 'unprotected' contracted the disease Similarly, of 5,579 'protected' nurses treating diphtheria cases and exposed to grave danger of infection, only 1·86 per cent were attacked, but of 166 known 'unprotected' nurses, no less than 24·1 per cent contracted diphtheria The average severity of the disease among inoculated persons attacked is also much less than among the uninoculated

Indo-Australian Fishes. Dr J D. F Hardenberg has discussed the species of the genus *Stolephorus* in *Treubia*, **14**, Livraison 3, 1934, and in the same journal he has two further papers on new or rare fishes of the Indo-Australian Archipelago and the fish fauna of the Rokan Mouth. *Stolephorus* is a genus the members of which are caught in coastal and estuarine waters Breeding along the coasts, their eggs are rarely found out at sea, but the adults may live in the deeper open sea waters, and there is evidence of migration not fully understood Many of them are good for food, the well-known red or Macassar fishes being coloured artificially with a fungus added during preparation. The author has discovered several new forms which he has studied

in great detail—nine species in all. He suggests from the results of these investigations, and in accordance with the embryological data found by Dr. Delsman, that the long slender forms of the open sea with a high total number of vertebræ and the anus having a backward position are more primitive than the higher coastal forms with fewer vertebræ and the anus farther forward. In agreement with this, he states that it might be concluded that there had been during the evolution of the genus a migration from the open sea towards the coast and into the tidal rivers.

Migrations of Mule Deer. The summer range of the Rocky Mountain mule deer, *Odocoileus hemionus*, lies along the higher ridges at elevations of 4,000–12,000 ft., but in winter it descends, as a rule, to the lower foothills, from 3,500 ft. near the lower limit of the yellow pine forest to 1,500 ft. in the oak covered sides of the interior valley of California (Joseph S. Dixon in *California Fish and Game*, **20**, 1934; now published separately). Various factors contribute to this migration, the autumn and spring journeys of which may together cover one hundred miles. Food is an important item: if suitable food is available, some or all the deer may not migrate, and food considerations seem to outweigh the effect of low temperature. But a heavy fall of snow, by making food plants inaccessible, becomes a main factor in determining the autumn migration from the high ground. It also compels the deer to move to open hill sides where they can move freely, and thus may enable them to obtain a livelihood on a winter range where forage is relatively sparse; but, most important of all, it adds to their chances of escaping from their enemies, the coyote and the cougar. The deer appear to realise that they are at a disadvantage against these carnivores in deep crusted snow, and although in some such areas food, in the form of wind-broken branches, remained abundant, they were avoided by the deer.

Larval Trematodes in Terrestrial Molluscs. W. Adam and E. Leloup have brought together (*Mem. Mus. Roy. d'Hist. Nat. Belgique*, No. 62, 1934) the records in the literature on the larval trematodes found in terrestrial molluscs, and have added critical and explanatory observations on them. They point out that the trematodes belong for the most part to the subfamily Brachylaiminæ (= Harmostominæ), and that the determination of the larval stages is almost impossible because of defective descriptions. The authors summarise in tabular form the measurements and other data available on the adults of the species of *Brachylaima* the larvæ of which are found in terrestrial molluscs, add a similar table for the larvæ, and a third table showing the trematodes recorded in terrestrial molluscs (except the Succineidæ). They record their observations on two species of *Brachylaima* from five helicine snails collected in Belgium.

The Embryonic Cell. The modern fashion for sectional monographs leads occasionally to the delimitation of subjects for treatment which leave the writer revolving almost *in vacuo*, and this seemed to have happened to Dr. René Souèges in the monograph on "La Cellule Embryonnaire" published as No. 208 of Actualités Scientifiques et Industrielles (Paris: Hermann et Cie). He expressly disclaims any intention of dealing with the phenomena of fertilisation or of subsequent embryonic development, and there remains very little to say in these 60–70 pages upon the plant oospore. It is probably very useful to have our ignorance of this all-important cell thus clearly exposed, and such problems as its polarity of organisation, the persistence of such structures as plastids, vacuome and chondriome are discussed very interestingly. Dr. Souèges goes a little beyond his own prescribed limits when he makes the interesting point that cell divisions follow most rapidly in Angiosperm oospores when these are associated with an endosperm also built of cells; when the endosperm remains for a long time a tissue with many nuclei without separate walls, then the oospore is slower to continue its development.

'Brown Spot' Disease of Turf. A short article by Dr. F. T. Bennett, in the *Gardeners' Chronicle* of February 23, describes a disease of grass turf known as dollarspot in America. It has been assumed that *Rhizoctonia solani*, the fungus causing *Rhizoctonia* disease of potatoes, was a common cause of brown spot maladies of turf. Dr. Bennett shows, however, that this is rarely the case in England, where another species of *Rhizoctonia*, named provisionally *R. Monteithianum*, is responsible for most of the damage. No spores of the fungus have yet been discovered, but it propagates itself readily from pieces of mycelium and sclerotial flakes. These may be blown by wind, and can withstand storage for fifteen months or more. Cultural characters of the fungus on artificial media, and symptoms of the disease on lawn turf, are described.

Gaseous Transfer of Silica. In *Economic Geology* (pp. 454–470; 1934), E. Ingerson discussed in a most stimulating way the problem of the possibility of transfer of 'insoluble' oxides by solution in gases at supercritical temperatures. That the process is a real one, and of fundamental importance in the genesis of both ore deposits and igneous rocks, is indicated by some experimental results recorded by F. V. Syromyatnikov (*Econ. Geol.*, pp. 89–92, 1935). The object of the study was the synthesis of serpentine from magnesium hydroxide (in the upper part of an autoclave) and silica and water (in the lower part of the autoclave). Silica was transferred upwards by water (gas) at temperatures of the order 400° C., and in some of the experiments Fe_2O_3 was also found to have migrated upwards. A sample of gas with 'dissolved' SiO_2 and Fe_2O_3 was condensed and analysed. The amounts found were 0·74 gm. of SiO_2 and 0·90 gm. of Fe_2O_3 per 1,000 gm. of water. Another point of interest is the proof that more silica was carried up, and fixed as serpentine, than was present at any given time in the gaseous solution. Hence diffusion of silica through the gaseous medium must have occurred.

New Zealand Pastoral Industries. A monograph on the pastoral industries of New Zealand by Dr. R. O. Buchanan is the first publication of the newly established Institute of British Geographers, which appears along with the *Transactions* as Publications Nos. 1 and 2. The treatment of the subject is mainly economic, and goes at length into questions of labour, marketing and prices; but certain facts of geographical importance emerge. The whole of the occupied area of the country seems to be suited for both cattle and sheep, but almost everywhere there is a more or less pronounced bias, in which

local geographical conditions play a part, in favour of one or other branch of the live-stock industry Conditions favouring cattle, which means dairy cattle since the world situation does not favour beef export, are low elevation, easy relief, rich soil and frequent, dependable rainfall Absence of these factors, especially the topographical ones, leads to predominance of sheep The monograph is well illustrated by maps and statistics, and is furnished with a detailed bibliography.

Ignition of Firedamp in Coal Mines. We have received papers Nos. 89 and 90 from the Safety in Mines Research Board, the former headed "The Ignition of Firedamp by Broken Electric Lamp Bulbs" by G Allsop and R. V. Wheeler, and the second headed "The Ignition of Firedamp by Coal-Mining Explosives" by C A Naylor, W. Payman and R V Wheeler The former is somewhat inconclusive. It is pointed out that under certain conditions the heated filament of an electric lamp after fracture of the glass bulb can ignite firedamp, and experiments have been carried out by the Research Board to see whether it is possible from the appearance of a tungsten filament to determine whether or not the filament has been burnt out in the presence of air (possibly air and firedamp mixed) and may therefore have originated an explosion Whilst the condition of the filament, whether oxidised or not, can be determined, the results are by no means conclusive The second paper gives a historical review of experiments on the Continent on the use of cooling salts for preventing explosives from igniting firedamp. It seems that an explosive sheathed in sodium bicarbonate is effective and practicable in this respect, and that the sheath does not interfere with the action of the explosive

Insulators of High-Voltage Transmission Lines. It is now well known that when the insulators of high-tension lines are subjected to an atmosphere loaded with industrial or saline matter, the deposits they receive frequently cause 'faults' on the line owing to 'flashovers' at the normal pressure In a paper read to the Institution of Electrical Engineers on March 20 by W. J. John and F M Sayers, it is stated that these flashovers are usually due either to the insulators getting coated with dirt or grit if near an industrial neighbourhood or, if near the sea, to a coating of salt To prevent faults forming, it is necessary to keep the insulators clean, as the deposit may increase rapidly. In some cases an ounce of matter has been collected from an insulator after only a few weeks service When it is an industrial deposit, experience has shown that all faults occur during fog and mist, and that all insulators which fail are covered with a deposit of carbon. It has also been noticed that no faults occur during or after rainfall Normal rainfall keeps the insulators reasonably clean This shows that the insulation can be improved by designing the insulator so that a large length of the leakage path is exposed to direct rainfall Although rain can wash deposits away, it unfortunately provides a wet surface which forms by itself a leakage path. Similarly wind blows the deposits away, but it also brings grit and dust to them. Hence the good and bad effects of wind and rain have both to be taken into account when designing insulators Salt spray is deposited when near the sea in moist sticky patches on their surfaces When dew falls a conducting film of salt moisture is formed which may lead to sparking giving excessive leakage current and so cause the protective gear to operate and interrupt the supply. An important conclusion the authors arrive at is that insulators of different designs may be advisable along different sections of the transmission line

Cataphoretic Velocity of Colloid Particles. Measurements of the cataphoretic velocity of colloid particles made by Messrs G N. Mukherjee and S G Chandhury, University College of Science and Technology, Calcutta, since 1923 and published in the *Journal of the Indian Chemical Society* from time to time, have indicated that the concept of the 'critical coagulation potential' is of doubtful value, since the value of the cataphoretic velocity at which coagulation occurs may vary very considerably according to the electrolytes employed Furthermore, coagulation may occur when the velocity is greater than that of the original sol The forms of the curves relating the cataphoretic velocity to the electrolyte concentration show no correlation for various electrolytes of differing valencies, whilst the velocity may often increase at high concentrations of univalent coagulating ions, especially near the stage of rapid coagulation Some experiments with arsenious sulphide sols, made by Mr K D Bhaback, have shown that on adding electrolytes, the cataphoretic velocity increases with time as aggregation proceeds, and falls sharply on coagulation This increase of cataphoretic velocity with aggregation confirms the experimental conclusions of Robinson (*Proc. Roy. Soc*, A, **143**, 130, 1934) who observed a similar effect in the case of particles of benzopurpurin B.

Alchemy at the Time of Dante. In a recent issue (pp 411–417, 1934) of the *Annales Guébhard-Séverine* (Institut Guébhard-Séverine, 4 rue du Seyon, Neuchâtel. Issued free), Prof J Ruska gives a brief survey of Latin alchemy of the first third of the fourteenth century. It is to this period that he would ascribe the composition of the celebrated "Summa Perfectionis Magisterii", a work which he says has nothing in common with the genuine books of the Arabic Geber. A treatise of the same period, but one which in argument and exposition is in marked contrast to the "Summa", is the "Margarita Pretiosa Novella" or "New Pearl of Great Price" of Petrus Bonus of Ferrara This is an introduction to alchemy, and was completed at Pola in 1330. Although the author apparently had some knowledge of practical chemistry and metallurgy, the book as a whole is an uncritical justification of alchemy on philosophical and metaphysical grounds. Its value to the historian of chemistry lies in the numerous and interminable quotations from previous authorities, which render it a rich mine of discovery in the detailed study of the influence of the older alchemists The principal authorities are the pseudo-Rhazes, the "Turba Philosophorum" and the "Summa", the paradox of the equal esteem accorded to the last two is explained by the fact that Petrus Bonus appreciated the value of the "Summa" but wished also to appeal to the venerable authority of the "Turba". As usual, the book concludes with a solemn assurance that it contains nothing but the pure truth. Prof. Ruska points out in his closing paragraph that the fourteenth and fifteenth centuries now form the most obscure period in the history of chemistry, and hopes that the problems they present may attract the young generation of chemists.

X-Ray Single Crystal Photographs of Insulin

By DOROTHY CROWFOOT, Department of Mineralogy, Oxford

SINCE insulin was first prepared crystalline[1] in 1926, several efforts have been made to obtain X-ray photographs of the crystals The first attempts of W. H. George[2] by the powder method failed to show any pattern indicative of a crystal structure, and though later long spacings were reported by G. L. Clark and K E Korrigan[3], it was impossible to base any unambiguous interpretation on their results The fact that pepsin could be made to give a single crystal X-ray diffraction pattern[4] suggested that the problem of insulin, which is in many respects a more stable crystalline species, could be attacked in the same way if large enough crystals could be grown. This was made possible by D A Scott's study of the crystallisation of insulin in the presence of salts of zinc and of other metals[5].

The crystallisation was therefore carried out by a modification of Scott's method from a phosphate buffer solution containing a little acetone and some zinc chloride at a pH of 6 2–6 5 The solution was cooled very slowly from 50° to room temperature over a period of three days, at the end of which time sufficiently large crystals had grown

The crystals have the form of very flat rhombohedra which often grow in pairs united at the ends of their trigonal axes The larger ones present the appearance of six lobed stars and are as much as 0·2 mm. across and 0 05 mm thick. These show a positive uniaxial figure when viewed along the trigonal axis The crystals prove to be perfectly stable in air (unlike pepsin) with unchanged birefringence and reflecting power, and it was accordingly possible to examine them dry by X-ray methods

Three series of X-ray photographs have been taken on three separate crystals, one rotating about the trigonal axis and the others about the normals to (10$\bar{1}$0) and (11$\bar{2}$0). Examples are shown in Fig 1. Copper $K\alpha$-radiation was used and exposure times of about 15 hours for a single 5° oscillation photograph with a plate distance of 6 cm. The crystals have so far proved unaltered by exposure for more than 100 hours to X-radiation The photographs taken indicate a simple rhombohedral cell of a 44·3 A. and α = 115° correct to about 2 per cent This referred to hexagonal axes corresponds to a cell three times as large with a = 74·7 A., c = 30 6 A, which shows no halvings but those required by the rhombohedral lattice The structure may also be described in terms of a pseudocubic body-centred cell twice the size of the primitive cell with a = 47·7 A., α = 103° 6′. No planes of symmetry are present and the space group is therefore $R3$ The cell molecular weight calculated for the primitive rhombohedral cell and the density 1·315 measured by Dr. Eyer[6] is 39,300 ± 800. (Density measurements on the actual crystals used gave 1·306 ± 0 003) As Abel has measured the water lost by heating the crystals at 104° in a vacuum at 5·35 per cent of the air-dried weight[7], the weight of insulin in the cell (cell molecular weight—water of crystallisation) may be deduced as 37,200, which is very close to the weight of one molecule of insulin reported by The Svedberg[8].

It therefore appears that the crystal unit cell contains only one molecule of insulin, although a cell containing $3n$ sub-molecules is not excluded by the X-ray data The laws of crystal symmetry rigorously applied would require this molecule to have trigonal symmetry, but it is possible also that the crystal attains apparent trigonal symmetry by a statistical regularity of arrangement of molecules about the lattice points, or that the X-ray effects so far observed are first approximation mass effects to which further work may add a fine structure, due to the arrangement of the atoms within the molecules, which our methods are as yet insufficiently delicate to detect The measurements obtained do, however, fix quite definitely the arrangement of the molecules with respect to one another and their approximate size and shape, since this follows directly from the crystal lattice, while the variation of the intensities of the spectra strongly suggests that the arrangement of atoms within the molecules is also of a perfectly definite kind

The crystal structure of insulin is of an eight co-ordination type, as the possible reference to the pseudo-cubic body-centred cell of twice the size most clearly indicates Each insulin molecule is

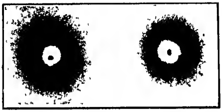

FIG 1 X ray photographs of crystalline insulin (a) Rotation axis normal to (11$\bar{2}$0), beam direction 0°–5° from ∥ (10$\bar{1}$0) (b) Rotation axis [0001], beam direction 0°–5° from ∥ (10$\bar{1}$0)

surrounded by eight others, two at the short distance of 30 A. above and below along the trigonal axis, and six at the longer distance of 44 A along the edges of the primitive rhombohedron The shape of the molecule therefore appears approximately as an oblate spheroid of diameters 44 A and 30 A D. A. Scott gives the atomic percentage of zinc in insulin crystals as 0 00795, or 3 atoms of zinc per molecule of insulin[9] It therefore seems reasonable to suggest that these atoms are required to bind the molecules into nets parallel to the c plane, one between each pair of insulin molecules along the six points of contact, the closer linkage along the c axes being due to other causes This would provide some explanation of the rôle played by zinc and other bivalent metals in promoting the crystallisation of insulin.

It is of particular interest to compare this crystal structure of insulin with that which may be deduced for pepsin from the X-ray measurements previously reported. It has been found that the true cell of pepsin has a c dimension three times as long as that at first suggested, namely, 461 A., and that the structure should probably be referred to rhombohedral axes[10] a = 162 A., α = 23° 50′ The first order of the reflections from the c plane to occur is, however, the 45th, while the strongest order is the 48th, which indicates that the most marked periodicity along c is one of only 9 6–10·2 A., very much the

same as the distance—10 A—between layers of atoms along the c axis of insulin It seems significant, further, that the length of a in pepsin—67 A—referred to the original hexagonal axes, is so similar to that of insulin—74 7 A. —when given hexagonal axes These two dimensions define a crumpled layer structure in which the molecules are arranged in networks of six sided rings of the non-planar cyclohexane type which occurs, for example, in diamond and wurtzite From the side of such a ring projected on to (0001), $a/\sqrt{3}$, or 38 7 A in pepsin, and the thickness of the order of 10 A, a length for one radius of the pepsin molecule may be calculated ≐ 20 A In insulin, the layers are so arranged that atoms in one fall as nearly as possible into the spaces of the one below, which makes a very compact structure In pepsin we may imagine that the layers of rings are slid relatively to one another, to bring atoms of the lower ring directly beneath those of the upper ring in such a way that each is approximately tetrahedrally co ordinated The effective depth of a single layer is then equal to the thickness of the ring system plus the diameter of a single molecule, and may be calculated to be 51 2 A, with a spheroidal pepsin molecule of diameter 41 2 A in this direction A combination of the crystallographically possible ways of sliding the ring systems is able to give the required length of c, nine times that of the depth of one layer and fifteen times the c dimension of insulin

This kind of structure proposed for pepsin is of a very much looser type than that of insulin Each molecule is surrounded by only four others and there are large channels through which free movement of water and dissolved substances may occur within the crystal structure On drying, such a structure would collapse, in agreement with the fact that, in contradistinction to insulin, the crystals of pepsin lose their birefringence on exposure to air and only show crystalline X-ray diffraction effects when immersed in the mother liquor Various observations[11] suggest that loose 4 co-ordination structure of this kind may be general among certain classes of protein crystals which belong either to a hexagonal type with an axial ratio about 2 3 similar to that of pepsin, or to a cubic type which shows diamond cleavages. Wherever the attraction between the adjacent protein molecules is of the same order of magnitude as that between the protein molecules and the medium, a low co ordination structure type may be expected. In insulin, on the other hand, where the molecules can be strongly attracted together with the assistance of metal atoms, the structure is very much more condensed and shows a high co-ordination number

I have to thank Prof Pyman and Messrs. Boots Pure Drug Co, Ltd, for a gift of the insulin used in this research

History of the Menthols

At a joint meeting of the Chemical Society, and the Glasgow Sections of the Society of Chemical Industry and the Institute of Chemistry, held in the Royal Technical College, Glasgow, on March 15, Prof. John Read, of the University of St Andrews, gave a lecture entitled "From Governor Phillip to *d*-neoisoMenthol: the Story of a Research, 1788–1934"

Prof. Read said that it was his intention to select a research paper and show what a rich background it possessed when given its proper setting in the world of things, men and affairs The paper in question closed a chapter, or perhaps more correctly a book, in the history of the important chemical family of menthols The usual source of ordinary menthol is the essential oil of the peppermint plant, *Mentha piperita*, which has been cultivated in Japan for more than two thousand years The first mention of crystalline menthol was made in 1771 by Gambius, a Dutch botanist It is now known that this so-called 'mint camphor' is a member of the first of four series of menthols Prof. Read and Dr. Grubb completed the tale of these four series in the University Chemical Laboratories at St Andrews on Christmas Day, 1933

In tracing the trend of events which led up to this chemical climax, Prof Read reminded his audience that Capt Cook landed in eastern Australia, hitherto unknown, on April 29, 1770 In his "Journal" he wrote of the landing-place: "The great quantity of New Plants, etc., Mr. Banks and Dr. Solander collected occasioned my giving it the name of Botany Bay" From the earliest days, indeed, the unique vegetation of this isolated land attracted the interested attention of visitors and settlers. Two-thirds of the native Australian flora belongs to the family Myrtaceæ, which is represented in Europe by a single species *Eucalyptus*, the outstanding Australian genus of this family, is a specialised form adapted to the barren and extra-tropical Australian areas, it developed after the separation of Australia from the tropical lands Typically Australian, it is virile, aggressive, and an excellent colonist, with all the characteristics of youth

Some graphic extracts from Dr John White's "Journal of a Voyage to New South Wales" followed. Dr White was surgeon-general to the First Settlement, under Governor Phillip, who reached Botany Bay with his fleet of marines, officials and convicts on January 20, 1788, after a voyage lasting eight months The "Journal" shows that the voyage had its romantic aspects as well as its hardships and notes of grimness. "May 28 Departed this life, Ismael Coleman, a convict, who, worn out by lowness of spirits and debility, brought on by long and close confinement, resigned his breath without a pang. August 31. James Baker, a private marine, received 200 lashes for endeavouring to get passed on shore by means of one of the seamen, a spurious dollar, knowing it to be so. . . Many of these young ladies [in a convent in Rio de Janiero] were very agreeable both in person and disposition; and by frequently conversing with them at the grate, we formed as tender an intercourse as the bolts and bars between us would permit of."

The fleet lingered for a month at Rio, before weighing for the Cape of Good Hope. It is said, although Dr. White does not endorse the statement,

that Governor Phillip took with him from Brazil some prickly pear plants, for the sake of the cochineal insects which infested them. These insects produced the scarlet dye used for the military uniforms of those days. Unfortunately, the insects appear to have perished during the voyage; thus the prickly pear, freed from its insect control, developed eventually into Australia's foremost plant pest.

At that time, oil of peppermint was a much prized specific; for in the first issue of the *Glasgow Advertiser*, dated January 27, 1783, it is stated in an advertisement that "this elegant preparation", sold by J. Gillies, bookseller, above the Cross, Glasgow, gives immediate relief "in Gouty and Cholicky Pains in the Stomach and Bowels, Low Headachs, and all Disorders arising from wind". Dr. White, being short of this oil, found a very efficient substitute in the essential oil distilled from a certain eucalypt growing around Port Jackson—now known as the Sydney peppermint, or *Eucalyptus piperita*. This is the first recorded instance of the distillation of a eucalyptus oil.

Many years later, in 1900, the Australian chemist, H. G. Smith, isolated the peppermint ketone imparting the characteristic odour to this oil, and called it piperitone. There are about three hundred species of eucalyptus, each kind—as shown by H. G. Smith and R. T. Baker—producing its own characteristic leaf oil: of these more than twenty secrete piperitone. It was then found that, by hydrogenation and dehydrogenation, piperitone could be changed into menthols and thymol, respectively, so that it has become a commercially valuable substance.

Eucalyptus piperitone is invariably a 'left-handed' substance. Soon after Prof. Read became associated with Mr. Smith at Sydney, in 1920, Prof. J. L. Simonsen, working independently at Dehra Dun, in India, discovered 'right-handed' piperitone in the oil of the Indian grass, *Andropogon Jwarancusa*. These two piperitones, of the northern and southern hemispheres, are identical, except that their molecules are related as object and mirror images.

One interesting result of later researches, carried out at St. Andrews, has led to a way of proceeding, by laboratory processes, from the 'left-handed' Australian piperitone to the 'right-handed' Indian piperitone. It has also been found possible by means of a complicated network of delicate reactions to utilise piperitone as a source of any one of the four series of menthols. Each of the four kinds of menthol exists in a 'right'- and 'left'-handed form, and methods have been devised for producing the 'right-handed' form of ordinary 'mint camphor', which always is 'left-handed' in Nature.

Crossing-Over of Sex Factors in *Lebistes*

WHILE the validity of the sex-chromosome mechanism in relation to sex determination is generally recognised, yet it has become clear from the work of Goldschmidt on *Lymantria*, Winge on *Lebistes*, and various other investigations in which intersexes and the crossing-over of sex factors occur, that genes influencing the sex towards maleness or femaleness are also found in the autosomes. Bridges' conception of genic balance applies to many characters, including sex, and it is necessary to suppose that there are many factors in all the chromosomes, some of which tend towards maleness and others towards the female condition. Various divergent views regarding the distribution of such genes in the X and Y and the autosomes are at present held.

In the little fish, *Lebistes*, in which there is a series of colour patterns inherited through the Y chromosome from father to son, Winge has shown also that the X chromosomes may be altered into autosomes, so that sex linked genes are inherited as ordinary Mendelian differences. By selecting masculine autosomal genes, XX males were obtained, and by backcrossing a race was produced in which both the males and females were XX in composition and the Y chromosome type of inheritance had been eliminated.

In a recent paper (*C. R. Lab. Carlsberg*, Série Physiol., 21, No. 1) Winge has carried the subject of sexual balance further. Probably in these fishes, as in pigeons, the difference between the sexes is small, so that the balance of the sex genes is easily upset. This is further shown by the fact that certain matings gave practically only females in winter but equal numbers of the sexes in spring. Nevertheless, conspicuous intersexes seldom appeared. Normally, females show no trace of the colour genes which are transmitted by the males in the Y-chromosome, but occasional females appear which show a trace of the male pattern and probably have several masculine genes. In a cross involving the *maculatus* and *lineatus* races, 7 XY females appeared having the *maculatus* spot. Crossed with XY males they gave, as predicated, 3 males : 1 female. Among these were fertile YY males which, when crossed with normal females, gave only male offspring.

There are no unequal pairs of chromosomes in *Lebistes*, so the X and Y must be of equal size. Among other conclusions reached are that all the genes in X are able to cross over to Y, and that the Y contains at one end a specific male-determining gene which is at the same time a gene for colour pattern. The X lacks this gene, but whether it possesses an allelomorphic feminine gene is undecided.

University and Educational Intelligence

ABERDEEN.—The honorary degree of LL.D. has been conferred on the following, among others: Prof. E. V. Appleton, Wheatstone professor of physics, King's College, London; Mr. W. H. Buckler, engaged in archæological work in Asia Minor; Lieut.-Col. A. T. Gage, formerly director of the Botanical Survey of India and superintendent of the Royal Botanic Gardens, Calcutta; Dr. J. C. G. Ledingham, professor of bacteriology, University of London, and director of the Lister Institute, London.

EDINBURGH.—A gift of £10,000 has been received from Mr. J. Albert Thomson for the purpose of establishing a commercial laboratory in the University. This will provide for the immediate requirements in staff and equipment for a laboratory providing the approved methods of training for students for the commerce degree, so that those who aspire to the higher positions in industry shall have an intimate working knowledge of all up-to-date office machinery and appliances.

LONDON.—The County Borough Council of West Ham has decided to make a grant of £2,500, payable over five years, towards the cost of the erection of the new buildings in Bloomsbury. The Worshipful Company of Plumbers has made a donation towards the cost of the Ceremonial Hall to be built on the Bloomsbury site.

St Andrews —The University Court has recorded a Minute on the occasion of the jubilee of the appointment of Prof D'Arcy W Thompson to the University (Nature, 135, 59, Jan 12, 1935) Tribute is paid to his outstanding worth and ability, not only in his own department of natural history but also in other departments of literary and scientific knowledge His election to the presidency of the Classical Association testified to his knowledge of and interest in the ancient languages and literatures of Greece and Rome, his election as an honorary member and as president of the Edinburgh Mathematical Society in recognition of his pioneer work in the application of mathematical methods to biological studies was a guarantee of mathematical ability of no mean order; and his work as adviser to the Fishery Board for Scotland, and as a delegate to the Bering Sea Fisheries Conference and to the North Sea Conference indicated his international reputation as a scientific administrator

Moscow State University will hold a summer school from July 16 until August 25 Instruction will be in the English language by an all-Soviet staff in twelve courses of thirty hours each, with occasional addresses by prominent Soviet officials The subjects of the courses include: Russian language (advanced), Russian literature, Russian arts, Russian education, Russian technology, Russian economics, Russian geography and Russian history (of the Soviet Union), administration of justice, public health and medicine, and the philosophy of dialectical materialism The students will also be able to choose one of six specially organised tours Last year's summer school enrolled 212 students

University College, London, continues to attract students from abroad in large numbers The recently issued annual report shows that of a total of 3,231 students enrolled in 1933–34, no fewer than 744, or 23 per cent, were from countries outside the British Isles, namely, 304 from other parts of the Empire and 440 from some forty foreign countries Among European countries Germany contributed 102, France 35, Switzerland 26 and Holland 19 students, while India was represented by 157, the United States of America by 45, South Africa by 31, Palestine and Australia each by 26. In the course of the year, the quinquennial visitation by members of the University Grants Committee took place, and from the summary of developments of the years 1930–35 prepared for presentation to the Commissioners, a number of interesting paragraphs have been reproduced in the report. One of these, relates to the great change that has taken place in the proportion between full-time and part-time students, the former having increased almost continuously since 1925–26 while the latter have diminished from nearly 1,600 to less than 1,100 The number of full-time post-graduate and research students has risen during the past ten years from 168 to 255 Several departments of the College were enabled, through the generosity of various benefactors, to offer hospitality during the past year to a number of scholars exiled from their homes in Germany, among them the distinguished chemist Prof. H. Freundlich. Annexed to the report is an address by Sir Josiah Stamp, delivered by him as Special Visitor on the occasion of the annual assembly of the Faculties: the subject is "The Management of Mind".

Science News a Century Ago

Lyell and Mantell

On April 13, 1835, Lyell wrote to Mantell: "I have been getting Dinkel to figure for me some fossil eggs of a turtle, found in the island of Ascension, imbedded in a hard rock something like that of Guadaloupe which contains the human skeleton It is clear that the eggs were nearly hatched at the time when they perished for the bones of the young turtle are seen in the interior with their shape fully developed On my showing the specimen containing seven eggs to Owen, of the College of Surgeons, he remarked to me that they were hollow, whereas the bones of reptiles want the medullary cavity Struck with this remark, and with the extreme hollowness of the bones, only to be compared to that of some Tilgate specimens which you have often shown me, I got Owen this morning to dissect for me a young turtle, not a fœtus, but so young that the mark of the attachment of the yolk was still a large opening He immediately showed me that the bones were not hollow, though we both remarked that the outside looked harder than the interior Owen has promised to get me a set of very young turtle's bones from the Zoological Gardens, and I am persuaded it will clear up a number of your difficulties"

The Zoological Gardens

"The Commissioners of Woods and Forests," said *The Times* on April 14, 1835, "have recently granted to the members belonging to the Zoological Gardens, in the Regent's Park, an extensive increase of land consisting of 10 acres, on the south side of the Park, which is now railed in Immediately an immense number of workmen of various denominations will be employed in levelling the ground, laying out, and planting elegant shrubberies; erecting superb habitations for various beasts and birds, which will be placed in them with all possible speed, from the society's collection at Kingston-on-Thames, where they have an immense farm On the completion of the intended improvements, these gardens will present to the public the most superb promenades in England, the whole of which will be completed in a few weeks. Since the commencement of the warm weather, the whole of the beasts and birds which were of tender habits have been removed from the menagerie, where they have been kept during the winter months, and are now exhibited to the public. During the present spring, these gardens will be considerably more frequented, on account of the immediate opening of the Regent's Park to the public. The grand broad gravel walk which passes through the Park leads to the Zoological Gardens"

The Franklin Institute

The forty-fifth quarterly meeting of the Franklin Institute, Philadelphia, was held on April 16, 1835. Various donations of books were stated to have been received, some of these being from the Society for the Encouragement of Arts, Manufactures and Commerce of London, and others from Faraday. In the report of the Board of Managers, it was said that "The Lectures of the Institute were closed on the 25th March last; the large number of the class, and the regular attendance during the season, clearly evince the interest taken by the members and the

public in this method of popular instruction, which, the Board indulge the hope, will long continue. A large portion of the time of the Committee on Publications has been industriously devoted to the improvement of the Journal, and its high reputation, not only throughout our own country, but also in Europe, should in the opinion of the Board, induce the members of the Institute, and the public generally, more extensively to encourage and patronize it . " Referring to the exhibition arranged for October 1835, the Board said "To awaken and create a laudable spirit of emulation and improvement, has always been the principal object of the exhibition of articles of domestic manufacture, and the Board rely with great confidence upon the support and co-operation of the mechanics and manufacturers of Pennsylvania, and of the United States, to render the exhibition of this year as interesting, attractive, and useful as those of preceding years "

The German Universities

On April 18, 1835, *The Times* stated that ' the number of these institutions is 19, 2 only of which, those of Berlin and Bonn, were founded in the present century; there were 3 established in the 14th century, Heidelberg, Prague and Vienna, 6 in the next century, 2 in that which succeeded, and 3 each in the 17th and 18th centuries The earliest founded was of the Protestant religion, the last for both Protestants and Catholics Of the whole number there are 11 Protestant, 5 Catholic and three mixed The greatest number of professors is at Vienna, where there are 79; the least at Erlangen and Kiel, each having 29 The greatest attendance of students is at Vienna and Berlin—nearly 2,000 each, the least at Rostock, 110, the number of professors at which are 34, very nearly one master to 3 students, and at Kiel, where there are 29 professors, and only 130 students. The universities next best attended by students to those named as having the greatest number are Prague, Leipsic, Breslau and Heidelberg, each of which has more than 1,000 students "

The Universities and Technical Training

PROF MAJOR GREENWOOD'S attempt to assess the functions of university education in the conditions of to-day in his stimulating presidential address on university education last November to the Royal Statistical Society, which has recently been published (*J Roy Stat Soc* , 98, 1 , 1935), deserves more than passing attention There has been much criticism of the efficiency of university education from an industrial point of view, and what has been said about the evils of specialisation and the shortcomings of the graduate in some highly specialised branches of knowledge has scarcely been too strongly expressed It must be remembered, however, that the graduate is largely the product of a system, and in the average man his merits and demerits at this stage are less the outcome of personal idiosyncracy than the result of the system under which he has been trained

This indeed has been fully recognised in such recent discussions as those before the Glasgow Section of the Society of Chemical Industry on the "Education of the Industrial Chemist", or that following Dr Underwood's address on "The Chemical Engineer and his Training for Industry" before the Manchester Section of the same Society Both schools of thought to be found at the present time are opposed to excessive specialisation before entering industry The difference between them lies rather in that one school would confer the technical knowledge and training after entering industry, while the other wishes to carry university or technical training to a point at which the graduate is almost immediately of direct service to industry

The existence of such divergent opinions is a matter of some embarrassment to those responsible for educational policy at the present time, particularly that of the technical colleges Generally speaking, it is only the large companies or combines that can afford to devote the first six months or year after a graduate enters their service to definite training courses calculated to give him a grasp of the industry and to test his qualities and particular gifts The smaller firms require men who can offer an immediate return, if only in the fulfilment of routine duties while gaining a modicum of experience. To them it is highly important that the graduate should have had some broad training in the particular branch of technology underlying their industry.

The comparative indifference of the larger firms to training in technology when selecting staff cannot but have a considerable effect upon the training given in the technical colleges, particularly in the full-time courses, and there is already evidence that even an honours degree in a branch of technology has no advantage over an honours degree in a branch of science when the general training accompanying the latter has been broad and sound Moreover, it was evident in the discussions at Glasgow that the possession of a 'pass' degree with its grounding in several branches of science is regarded with increasing favour as a satisfactory qualification for entry even to the smaller firms, where promotion may be to chief chemist or engineer, works manager, or the like A recruit is not expected to possess a large stock of practical knowledge, but high scientific qualifications and a capacity for independent work

These reasons alone may lead to some change in the functions which technical colleges fulfil in the social and industrial conditions of to-day Apart from this, there are other factors which are tending to change the functions of university education also The emphasis on the utilitarian aspects is diminishing Education is no longer supported, as Prof Greenwood pointed out, on the ground that the technical efficiency of the educated is in the long run greater than that of the merely instructed, that an educated nation would be better fitted to secure advantages in the international struggle for markets than an uneducated nation Already there is a demand for higher education for its own sake, not for some material or social advantage it confers but as a path to happiness

This change is highly significant. It bears closely on the problem of leisure and on the raising of the school-leaving age It is one of the weightiest objections to the trade continuation school advocated by Sir Kenneth Lee and others as alternative to raising the school-leaving age The more nearly education at whatever stage succeeds in teaching principles, not practice, in training the mind without neglecting to train the hand, and in sending out those whose training and outlook enable them to attack with confidence the new problems that are perpetually arising, the more it will provide society with those who are capable of adapting themselves quickly and harmoniously not merely to particular industrial positions but also to the utilisation of leisure and the problem of citizenship generally

Such questions cut deeply into our whole educational system As Mr H T. Tizard pointed out in his presidential address to Section L (Educational Science) at the Aberdeen meeting of the British Association last year, it is no simple matter to encourage a broader education. A policy of making scholarships in science deliberately available for those who have not specialised in science, which the Imperial College of Science and Technology has initiated, would do much to discourage that excessive and premature specialisation in science at school which is a root cause of the lack of culture and sense of values possessed by many honours graduates in science to-day. Such a policy, however, cannot succeed unless it is supported both by the schools and the larger universities, and as Mr Tizard trenchantly remarked, if it is not considered worth while to reform the university matriculation examination in this way, criticism of the general education of the science student loses most of its point

There is a further point to be considered in this question of education for life, for leisure as well as for industry Prof Greenwood suggested that the total collapse of political freedom throughout the greater part of Central and Eastern Europe is mainly due to the fact that the populations were not educated at all Instruction may be confused with education when it is a mere question of technical skill for some particular occupation Such confusion can never exist when we consider the effect on the whole man, and recent events in Germany have made patent the defects in elementary instruction as compared with education Moreover, the evidence suggests that the present rulers of Germany, so far from making higher education more accessible to the public, are deliberately making it less accessible

These considerations are not lightly to be dismissed. The dissociation of higher education from industrial or social status may be an essential element in a policy which will provide society with citizens possessing the requisite background of knowledge in this scientific age, for the adequate discharge of civic duties no less than to meet industrial needs. The mere increase of technical efficiency will not avert disaster. The capacity to live fuller and happier lives, to enjoy leisure with less dependence on the service of others—these are closely related to the question whether civilisation is to gain control over the forces placed in its hand or whether it is to relapse as a whole into comparative barbarism.

The functions of a university in the world of to-day cannot be considered apart from the functions of education as a whole It is no longer sufficient for the universities to provide society with the leaders it requires in the professions, in industry or in the State More and more it has to assist in developing that background against which constructive virile citizenship is possible, to provide in every sphere of life the mental stimulus and corrective to those habits of mind and tactics which, carried over from an old order, are obstacles to the development of the new It is in this sense that, as Col A G Lee remarked at the recent Conference of Industrial Physics in Manchester, we require more social workers, and that organisations such as the Institute of Physics should seek to awaken the country to the necessity of adjusting physical discoveries to the rate of advance in economic affairs, so that we can enjoy the leisure and wealth created by the physical sciences

The ideals of a university set forth by J H Newman, Mark Pattison and Walter Bagehot or J S Mill, in essentials, differ little from those expressed by Dr Abraham Flexner or Prof Alexander in recent years Their functions, on the contrary, are rapidly changing, and the future of civilisation depends largely on the skill with which the functions of the universities are adapted to the needs of to-day Mechanical organisation is never an adequate substitute for effective social organisation or for a sound biological adaptation, and Prof Greenwood's address should stir scientific workers to probe far more deeply into the question than merely to discuss the best training to be given to chemists or physicists for industry From the universities, after all, must come once more that floodtide of intellectual life, that spirit of unprejudiced search for truth, which will disdain merely to copy, and will ensure that the mechanisation of life proceeding so fast, follows, not the economic or technical pattern of the past, but develops new structures adapted for the purposes of to-day, and releases for mankind a wealth of creative energy and intellectual power worthy of the discoveries which gave them birth

Reviews

Bull-Worship in Ancient Egypt

The Bucheum By Sir Robert Mond and Oliver H Myers With Chapters by T J C Baly, D B Harden, Dr J W Jackson, G Mattha and Alan W Shorter, and the Hieroglyphic Inscriptions edited by H W Fairman (Forty-first Memoir of the Egypt Exploration Society) Vol 1 · *The History and Archæology of the Site* Pp. xii+203 Vol 2 · *The Inscriptions* Pp iii+92 Vol 3. *The Plates* Pp iv+173 plates+iv. (London Egypt Exploration Society; Oxford University Press, 1934.) 50*s* net

NO animal has had a more consistently honourable place in the life of the Egyptians than the ox The earliest human settlements contain remains which indicate the domestication of cattle, while the special treatment of skeletons in an associated cemetery suggests some sort of veneration already at this date Before the historic period, ox-headed amulets have appeared The famous ceremonial palette of the First King of the First Dynasty depicts the Pharaoh as a bull trampling his enemies underfoot—a conception to be made explicit 1500 years or so later, and maintained thereafter until the end of the Dynasties, by the inclusion of a "Strong Bull" name in the royal protocol. Hathor was not the only cow-goddess, and mythology could show other bulls and cows who did not claim the full status of divinity To-day the buffalo, though often with a camel for yoke-mate, draws virtually the same plough as is to be seen behind the cattle on the walls of tombs of the Old Kingdom Small wonder that the three sacred bulls, the animal theophanies of three different and major gods, of the separate worship of which we are certain, are among the most important animal cults known in ancient Egypt.

Bull-worship in Egypt is in fact a large subject for which a great deal more evidence and study is required before much can be said about it, and even the elaborate researches underlying the three volumes under review admittedly only approach the subject Of the three great cults, that of Apis at Memphis-Saqqarah is the best known, and has left behind the most concrete remains But the great underground cemetery of these bulls was excavated more than eighty years ago, when methods were less scientific than they are to-day, and a mass of invaluable information, from a site which was for many reasons much richer than that of the Bucheum, was lost. The ancient worship of Apis, however, was used by the Ptolemies as a basis for a mixed mystery cult for their Greek followers, and in the new name of Serapis spread beyond the borders of Egypt. While the crumbly soil of the Bucheum easily gave way, frequently before the

excavator's eyes—as it evidently must have done while the mausoleum was still growing—the vaults of the Serapeum remain to-day one of the important sights of Egypt The burial stelæ of Apis have given us invaluable chronological checks for the twenty-sixth dynasty His worship can be shown to go back to the Old Kingdom In short, the sum of our knowledge of Apis, always the most important, is much greater than that of Buchis, perhaps the least of the three sacred bulls Hence a brief account of Apis has been given in "The Bucheum" as the basis of the attempt to reconstruct the story of Buchis On the other hand, much that was known about Apis at second hand only has been confirmed by the actual remains in the cemetery of Buchis, while our knowledge of the original appearance of the Apis burials and their method have been very largely supplied by the careful excavation of the other

From Mnevis, the bull sacred to Rē' at Heliopolis, little help is to be had Only two of his tombs have been opened But from contemporary literature, it appears that his cult was older and more important than that of Buchis—as old, probably, as that of Apis

There is singularly little material from which to write the history of Buchis Under that name he does not come into existence until the reign of Nekhthorheb of the last native Egyptian dynasty --a king who gave marked encouragement to the indigenous cults of Egypt and especially that of Apis The name Buchis (*Ba-hr-khet* or *Bakhe* in Egyptian), however, seems to have been no more than an enhancement of the status of a sacred bull which had represented from the eighteenth dynasty, if not from the twelfth, the God Mentu of Thebes in four different appearances, corresponding with four different towns of the Thebaid

At the same time, it is evident that he was even more intimately connected with Rē'. But while bull worship in Egypt was always connected with solar religion, it is by no means clear that Mentu himself was originally a bull-god. Anterior to the twelfth dynasty, it is not possible to trace the bull that became Buchis, unless we assume that his worship was instituted at that date as a southern counterpart of Mnevis For Hermonthis, the seat of Buchis eventually, was called in Egyptian 'Southern *On*', while Heliopolis, or *On*, in the north, was the home of Mnevis

"The Bucheum", then, is the definite publication of the excavation of the cemetery of the sacred bull Buchis and that of the cows who had borne Buchis bulls. The cemeteries lie in the desert two or three miles west of the site of Hermonthis (modern Armant) and about ten miles south of Thebes. Their discovery (in the archæological sense) was not an accident. Native plunderers had already placed objects now recognised as from the Bucheum on the antiquities market, and there were stories going about which might or might not mean anything Armed with these fragments of evidence and the brief references to the bull in classical authors, Mr W B Emery, at that time excavating among the tombs of Gurneh for Sir (then Mr) Robert Mond, spent the greater part of his leisure examining the desert nearest to the village of Armant, where he was confident a second Serapeum was to be sought It was a carefully worked-out investigation, and the first fortnight's work showed the excavators that they had landed on top of the cows' vaults The next season, again initiated by Emery, though under the general direction of Frankfort, they dropped directly on to the most sumptuous of the bulls' burials The success that followed, and finds completion in the present publication, has no doubt obliterated from most minds the memory of the almost universal scepticism, in the face of which Sir Robert Mond decided to move his dig from the classical site of the Theban necropolis to a barren stretch of ground which his colleagues promised would yield only a mare's nest

If unusual courage and judgment was shown at the outset, the conclusion in the form of the publication is even more remarkable Excavation reports are as a rule highly technical affairs and dull enough as general reading The excavation of Buchis yielded about forty tombs of bulls and as many cows, all subterranean Little is now to be seen on the site, and except for the stelæ, not much more in museums There are singularly few concrete remains—for a number of reasons—of what was a most important phase of Egyptian life With one very interesting exception, the sum of our new knowledge resulting from the excavations is confined to a comparatively small, though important, sector of the field of Egyptological research Yet it has taken three large volumes to say all this, and generally speaking, not only is the size of the publication justified, but also it may be said to constitute a step forward in archæological science, and to set up a new standard for future work

"The Bucheum" is an advance on previous excavation memoirs for two reasons First it is an attempt to deal fully and finally, in so far as the material is available, with the field of study illumined by the excavation of the Bucheum, not merely to record those excavations and draw inferences from them, *within a year or two after the close of work on the site* Secondly, the principle of seeking expert opinion on every detail of the find has been carried out in it to a greater extent than in any other work of this kind known to the reviewer. There are in fact thirty contributors to

the book, specialists ranging from Coptic to musical instruments, from petrology to Arabic inscriptions, besides another score of experts named whose opinions have been taken on specific points To Mr O H Myers has fallen the task of holding the team together, and since there was something in the nature of pioneering about it, some unevenness was to be expected and may be passed over Mr Myers has also contributed, as director of the excavations during the last two seasons' work, the bulk of the chapters on the history of Buchis, the site, architecture, etc, together with a very elaborate study of the Demotic ostraca, full transcriptions and translations of which form a separate chapter by Mr G Mattha in vol 2

The outstanding contribution to the work, both for its scholarship and as the main source of new knowledge acquired, is the chapter by Mr. H W Fairman on the hieroglyphic inscriptions The bulk of these, and the most important, are the stelæ set up to each bull, on which are recorded the dates of their birth, installation and death, together with their ages Here and there an additional comment of historical or sociological importance creeps into the more or less stereotyped formulæ in which the ceremony of installation is described Once, by the mention of a queen in a royal titulary, whom Fairman proves to be none other than Cleopatra VI, we are lifted for a moment out of the academics of a little-known animal cult in Upper Egypt, into the heart of international politics in a world disputed by Antony and Octavian How significant such a small detail may be is to be read in Mr. W W Tarn's chapter on "The Triumvirs" in vol. 10 of the "Cambridge Ancient History", where Cleopatra's installation of a new Buchis at the beginning of her reign provides important evidence for her popularity with the Egyptians and for her support of the native religion

Sir Robert Mond has set up a new standard in archæological publications, which will not easily be repeated. The expense involved in the production of such a work, requiring considerably longer and more concentrated research than can be squeezed into the leisure between successive excavation seasons, is in itself beyond the purse of most bodies such as the Egypt Exploration Society, which was responsible for the greater part of the excavation and for the publication of "The Bucheum" Sir Robert not only provided those funds, but has also allowed the book to be published at a price within the reach of students, to whom a three-volume memoir of this size would normally be unavailable. It is in fact a standard which can only be maintained so long as archæology can find patrons.

The New Knowledge of Hydrogen

Orthohydrogen, Parahydrogen and Heavy Hydrogen. By Dr Adalbert Farkas (Cambridge Series of Physical Chemistry) Pp xiv + 215 (Cambridge At the University Press, 1935) 12*s* 6*d* net

WHEN chemists are told that since the principles governing the outer sphere of the atom are now established, there is little interest left in pure chemistry, they should turn for comfort to contemplate our new knowledge on hydrogen The book under review will give them competent guidance

The first half of the book deals with the ortho- and para-modifications of hydrogen proper, the second (smaller) half with heavy hydrogen Whilst the former presents a well-established body of knowledge, the latter outlines the beginnings of a new, yet unlimited, field of research

The author, well known by his researches on ortho-, para- and heavy hydrogen, marshals the various features of his subject with equal ease The quantum mechanical theory and the spectroscopic evidence by which the existence of ortho- and parahydrogen were predicted, the delicate heat conductivity method by which the ortho and para contents of hydrogen are determined, the theory of heat capacity and of other thermodynamic properties of the two modifications are set out with equal precision The problems of chemical kinetics, arising from the wide range of observations on the conversion of orthohydrogen into parahydrogen are discussed with similar mastery of facts and theories

To the chemist, these various conversions are the most interesting part of the subject Not all conversions are based on atomic interchange between a pair of molecules Comparison with the reaction

$$H_2 + D_2 = 2HD$$

has now definitely established this fact

The interchange between the atoms of hydrogen molecules is caused by the contact with hydrogenating and reducing catalysts Comparison between the catalysed process of atomic interchange, and the catalysis of the chemical reactions of hydrogen, will show definitely whether this catalysis is based on a preliminary breaking up of the hydrogen molecule, or whether we have to envisage other methods of 'activation' of the hydrogen by the catalyst

A wider scope for the study of the atomic interchanges of hydrogen which accompany chemical reactions is opened by the discovery of heavy hydrogen The presentation of this discovery and of the rapidly growing knowledge derived from it embraces the most varied aspects, ranging from

nuclear disintegration to the metabolism of bacteria Here again we find theory and experiment presented with equal clarity

This review of our knowledge of heavy hydrogen will be welcomed just as much as the presentation of our knowledge of orthohydrogen and parahydrogen The linking up of both subjects in one volume may, however, have some disadvantages The rapid advancement of research on heavy hydrogen tends to make a review written to-day soon become obsolete It would be regrettable if this should endanger the future popularity of the book, the first half of which will probably retain its usefulness for a long time

The enduring value of the book lies in the fact that it sets an example for the new spirit of physical chemistry, in which the fusion of physics and chemistry, of theory and experience, should be complete

Introductory Logic

The Principles of Logic: an Introductory Survey By C A Mace Pp xiii+388 (London, New York and Toronto. Longmans, Green and Co, Ltd, 1933.) 12*s* 6*d*. net

MR MACE'S purpose is to help students who begin the study of logic, and to supply them with a mental discipline by acquainting them with genuine logical problems rather than by forcing upon them the technicalities of traditional exercises. The "Principles of Logic" will be found extremely valuable by all those who already know some logic But it is difficult to say whether beginners could master in one year the theories and problems so excellently treated in this book The increasing complexity of logical systems makes it more and more difficult to teach logic in its present-day setting to first-year students, who may not have much natural aptitude for the subject and cannot have the philosophical training which, in all fairness, should be assumed for a serious reading of Mr. Mace's book

The pedagogical problem involved concerns less the students or the teachers themselves than the actual status of logic in our educational system. In order to make sure that students master the rudiments of sound reasoning before attempting prematurely to deal with problems which may be beyond them even later on, lecturers have to check their natural inclination to acquaint their students with some fundamental developments of logic This difficulty could be easily redressed if logic were given a place in our schools

Without attempting to deal here with the various details of the theories so very ably analysed and explained, we may indicate two of the principal features of the book. A chapter on the "General Theory of Deduction" introduces in a simple way the principles of symbolic logic, and, secondly, the author has taken great pains in bringing together, often with important additions of his own, the contemporary efforts to improve Mill's theory of induction. Though Mr Mace treats his problems without exhibiting a partisan attachment to a school, he nevertheless favours the views of logical analysis as against the ontologism of the Aristotelian tradition, while, in the last chapter of his book, he seems to share a kind of pragmatism which may easily turn to scepticism. But after all, is it possible to have any logic without some conscious philosophical background?

Short Notices

Index Generalis Quinzième édition française. Annuaire général des Universités et des Grandes Écoles, Académies, Archives, Bibliothèques, Instituts scientifiques, Jardins botaniques et zoologiques, Musées, Observatoires, Sociétés savantes. Publié sous la direction de Dr. R de Montessus de Ballore. Pp. vi + F176 + US228 + BE232 + 1284 + 1921 to 2462. (Paris. Éditions Spes, 1935) 225 francs

THE "Index Generalis" began publication shortly after the close of the War, when "Minerva", hitherto the standard reference work to the learned world, had suffered considerable reduction of size. "Minerva" has developed since then into two portly volumes, but the price in English money effectually prohibits their general use except in the wealthiest of institutions. The "Index Generalis", now in its fifteenth year, is a useful single volume substitute.

For those not familiar with the "Index", its arrangement is a little peculiar. The first section deals with the university institutions of France and its colonies, including a brief statement on general entrance conditions and, under each institution, number of students, budget and a list of the staff with their subjects. These page numbers are preceded by the letter 'F'. Succeeding sections, each with fresh pagination and with the letters 'U.S.' and 'B.E' respectively, deal similarly with the United States and the British Empire. The remaining countries of Europe, Africa, America and Asia are covered in the next section, which again has new pagination, but without distinguishing letters. Succeeding sections, the pagination continuing, contain details of observatories, libraries, scientific institutions and learned societies respectively, the entries being arranged alphabetically by countries. Then comes the alphabetical index of the personnel named in the text, reference being facilitated by the addition to the page number of a numeral (1–8) indicating

position on the page. A useful list arranged by subjects gives the names of those willing to exchange publications, and there is a geographical index

The 1935 issue of the "Index" is now available, and the 'working part', the index of personnel, runs to 443 three column pages of small but clear type The volume should be of service to all who have occasion to deal with scientific and learned institutions The information published, for the insertion of which no charge is made, is obtained directly from the institutions themselves, and the editor, Dr. R de Montessus de Ballore, Sorbonne, Paris, 5, informs us that he welcomes corrections and additions to his valuable handbook We hope this hint will catch the eye of those responsible in the U.S.S.R for the lack of information from that country

Rayleigh's Principle and its Applications to Engineering · the Theory and Practice of the Energy Method for the Approximate Determination of Critical Loads and Speeds. By Prof G Temple and Prof W G Bickley Pp. ix + 156 (London Oxford University Press, 1933) 14s net.

PROFS TEMPLE and Bickley have exemplified and extended a principle put forward by Rayleigh so far back as 1877, a principle which, concerned primarily with the calculation of the fundamental frequencies of vibrating systems, has applications to problems of elastic stability, and to various equilibrium configurations of interest and importance to engineers. In the words of the authors, the principle may be enunciated briefly, thus "In the fundamental mode of vibration of an elastic system, the distribution of kinetic and potential energies is such as to make the frequency a minimum".

Suppose, then, we are faced with a vibrating system the fundamental frequency of which we find it difficult, or impossible, to compute Let us constrain the system to vibrate in a specified manner in which the mode of vibration is (mathematically) known, and approximates as closely as may be to the mode of vibration of the actual system We can, by an application of the energy method, calculate the frequency of this artificial system; and the frequency of the actual system will, in general, be less than (in some limiting cases, equal to) this calculated frequency. The difficult task of determining the magnitude of the error has been attacked by Dr Temple, and we are fortunate in possessing in such an easily accessible form the record of his very interesting results.

The power of the method is shown by a series of thoroughly practical illustrative examples, and the book, which is a very important addition to the literature of physics and engineering, has been written with a mind sympathetically disposed to the capacities of those weaker brethren to whom an austerely mathematical argument makes but little appeal. Which is not to say that the book lacks in mathematical rigour, but merely to hint that easier paths are provided for the less mathematically minded. A. F.

Physique moléculaire matière et énergie Par Prof. Victor Henri. Pp 436 (Paris · Hermann et Cie, 1933) 110 francs

THE present time appears particularly appropriate for an attempt to form a complete picture of our knowledge concerning matter and energy. Starting from the early controversies fought around the question of continuity and discontinuity, the author describes the origin of the atomic hypothesis, the idea of chemical elements and their periodic classification, and the methods of determining Loschmidt's or Avogadro's number This is followed by an account of the properties common to all chemical elements, a history of the atom and of its spectral manifestations. The essential features of radioactivity, radioactive elements and isotopes are set out in an easily intelligible and attractive form Throughout the book are scattered many historical data, useful formulæ and illustrative numerical examples Particular praise must be given to the line diagrams which are, with few exceptions, models of clearness

Handbuch der wissenschaftlichen und angewandten Photographie Herausgegeben von Alfred Hay Band 6 *Wissenschaftliche Anwendungen der Photographie* Teil 2 *Mikrophotographie* Bearbeitet von T Péterfi Pp ix + 432 (Wien und Berlin: Julius Springer, 1933.) 51 60 gold marks.

THIS book gives a very full account of the modern state of photomicrographic technique in Germany. It constitutes, in fact, not only a textbook of the practice of the various methods, but also a fairly representative handbook on the apparatus manufactured by the various optical firms

The trouble with a work of this kind is that its detailed character makes it difficult to read as a textbook It can only function as a reference book, but as such it cannot fail to be of use to a serious worker. It is well printed and illustrated, and those who have occasion to use photomicrographic methods will be indebted to its author for such a useful piece of work

Check-List of Birds of the World By James Lee Peters Vol 2. Pp xvii + 401 (Cambridge, Mass.: Harvard University Press London Oxford University Press, 1934) 17s. net.

THE appearance of the first volume of this most useful adjunct to the work of the scientific ornithologist has already been welcomed in NATURE It is a book purely for reference, consisting of a systematic list of all known birds, with the authorities for the names used and the distribution of each form The like has not been attempted on a world-wide basis for a generation, and as the plan and execution are admirable the completed work should be of great service This second volume covers three great cosmopolitan orders—which incidentally include most of the birds of special interest to sportsmen—the megapodes and game-birds, the cranes, rails and bustards, and the plovers, gulls and auks.

The Oxford University Arctic Expedition, 1935–36

By A R GLEN and D B KEITH

AN interesting feature of post-War university life has been the active part played by Cambridge and Oxford in exploration This activity has by no means been limited to a few places, and to mention only one or two of the places visited, Cambridge expeditions have carried out useful work in various parts of Africa and in Greenland, while Oxford expeditions have obtained valuable scientific results in South America, Borneo and Spitsbergen The first of this kind to spend a winter in the arctic was the British Arctic Air Route Expedition of 1930–31, and the expedition which was organised by Mr E E Shackleton and led by Dr G N Humphreys, now making its way from Etah to Ellesmere Land, is the first Oxford expedition to winter

In July, another Oxford expedition is leaving England to spend fourteen months on the north coast of North-East Land. It is being organised by Mr A Dunlop-Mackenzie; Mr A R Glen, leader of the 1933 Oxford University Arctic Expedition, is going as leader The personnel of nine is made up by three surveyors, two physicists, a wireless operator, a glaciologist, a doctor who will also be in charge of the marine biology, and a dog-driver The last, Mr Andrew Croft, was a member of the British Trans-Greenland Expedition of last year, and will be second in command of the present expedition

The sealer, the M S. *Polar* of Tromsø, has been chartered, and it is hoped that the north coast will be reached during the first week of August A base hut will be built near the head of Rijp's Bay, and after all the stores and equipment have been landed, the ship will return to Norway. The plans are to carry out a topographical and geological survey of the unknown north and east coasts and of as many of the northern and eastern islands as time and ice conditions permit. In addition to the surveys, researches on the ionosphere, atmospheric ozone, electrical disturbances and terrestrial magnetism, will be carried on at the base over the whole year, and two winter stations are to be maintained on the inland ice with the intention of trying to form an estimate of the present balance of glacial conditions, as well as investigating the crystallography of surface snow, firn, and of blue and white ice

FIG 1 The lake country of north-east Spitsbergen It is believed that similar country exists to the east of Rijp's Bay, and if so, it should be of considerable biological interest.

Finally, a fairly comprehensive biological programme is planned, and the land side of this, which will consist mainly of a study of the birds, will be under the direction of Mr D B Keith, while the marine work will be in the care of the doctor

In addition to general observations on the bird life, special attention will be devoted to four problems The first is that of the non-breeding years which seem to occur every fourth year in the Arctic It is probable that 1936 will prove to be one of these, and if this should prove to be the case, the gonads of selected species will be examined (and preserved) in May, June and July, and an attempt will be made to discover if there is any evidence that the non-breeding is connected with the weather conditions of the summer or of the previous winter. It has also been suggested that exceptionally late breaking of the sea ice, or late melting of lake ice, might cause interference with the food supply of the birds, and this, together with any other factor affecting the food supply, will be examined. In the event of 1936 not being a year of extensive non-breeding, estimates of the proportion of breeding to non-breeding birds will be made, and this may give interesting results, as it is a subject on which very little work has been carried out.

It is hoped that it will be possible to make a detailed study of the snow bunting throughout the breeding season, with special reference to territory Much work has been done and is being done at home on the breeding and territorial habits of closely allied species, and this should prove a valuable comparison, for not only is the habitat

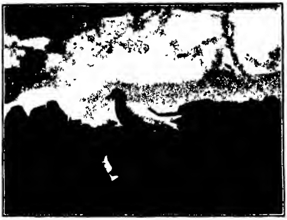

FIG 2 One of the first colony of ivory gulls to be discovered in western Spitsbergen by the Oxford 1933 Expedition

so vastly different from that of the species already studied, but also the snow bunting is the most northerly passerine and hence has no food competitors in the form of other passerines The bird distribution will also be analysed from the point of view of food supply and nesting sites

During the Oxford 1933 Expedition in Spitsbergen, Mr Hartley and Mr Fisher (*Geog J*, 84, Aug, 1934) carried out a detailed study of the marine feeding of sea birds, and correlated the facts with the conditions of the marine fauna investigated by Mr Stott The fulmar petrels and kittiwakes were found to have a feeding zone about 100 yards long and 50 yards across, close to the ice cliffs of the Nordenskiold Glacier, at a point roughly half way from either shore (Fig 3) This zone remained a permanent feature during July and August, and the normal number of kittiwakes was about 3,000, while that of the fulmars varied between 500 and 700, but these numbers rapidly decreased in the beginning of September From analyses of a large number of stomach contents, the food was found to consist almost entirely of the Euphausid *Thysanoessa inermis*, although an amphipod, *Euthemistes libellata*, occurred occasionally in small numbers It was also found that *Thysanoessa* was the basic food of Arctic terns, Brünnich's guillemots and little auks, and also had place in the food of puffins, although these were mainly fish-eaters, and of Mandt's guillemots, which were found to feed also on the general bottom fauna of the inshore zone Thus it is of the greatest importance to the bird population, and it is probably only through the blanketing effect of the silt brought down by en-glacial and sub-glacial streams that it is able to live in the extreme surface layer in this area As a large glacier flows from the west ice of North-East Land into Rijp's Bay, and as it is the only glacier with a sea face in the bay, it will be of the greatest interest to discover whether the phenomenon is repeated in this area, and also whether it occurs in the other bays of the north coast of North-East Land

The 130 miles of almost continuous ice cliffs on the east and south coasts may give interesting conclusions, especially as there are several islands off the northern part of the east coast which may offer suitable nesting sites It is not intended to repeat this study in the detail with which it was carried out in 1933, but rather to see if the birds in these areas resort to these definite feeding zones, and to discover what effect the zones—if any—have on the distribution of the birds The work will probably be correlated by observations on the marine fauna, and this will be under the direction of the doctor, who is the only member of the expedition not yet appointed

Little is known of the breeding habits of the Spitsbergen ptarmigan, and there are no skins of the bird in breeding plumage or of the chicks at the British Museum (Natural History) It seems likely that the birds breed on moderately high ground, and that they come down to the coasts and low unglaciated ground when the snow limit

FIG 3 Nordenskiöld Glacier sea face showing the cave in front of which was the zone frequented by fulmars and kittiwakes

becomes lower with the approach of winter Attempts will be made, therefore, to find their breeding places and to examine their winter distribution, as well as the change brought about in this by the approach of spring Some years ago, reports were brought back from the Ice Fjord region of Spitsbergen that there were remarkable

fluctuations in the numbers of the ptarmigan, but it is very possible that the reports of the scarcity of the birds were made on the evidence of the summer months, when the birds may have been on relatively high ground One of the parties of the Cambridge 1932 Spitsbergen Expedition spent some time in the Wijde Bay, and while there, found a considerable number of ptarmigan above the 1,500 ft level Only on one occasion, and then towards the latter part of August, were birds found below that height Similarly in 1933, the Oxford Expedition in the north-eastern part of the Ice Fjord found only one family of ptarmigan during July and August, but in September large numbers of the birds were found in the low valleys, the snow level by that time being at about 600 ft The reports of number fluctuations may thus, in part, be due to variations in the autumn weather conditions at the time when the ptarmigan are likely to be driven from the high ground by the approaching winter into the valleys, where they are most easily seen

It is hoped that it may be possible to bring back the skins of certain species required by the British Museum (Natural History) Some collecting will be undertaken with the view of ascertaining crop and stomach contents, and all birds shot will be examined for lice, as the parasites of arctic birds are very little known All bears and seals shot will likewise be examined for parasites Every effort will be made, however, to restrict the shooting and hunting to a minimum, as the history of the fauna of Spitsbergen during the last fifty years shows only too clearly the havoc wrought by indiscriminate slaughter, although the efforts of the Norwegian Government during recent years are meeting with a well-merited success

The general observations will include notes on such subjects as numbers, distribution, time of arrival and time of departure, and as no observations of this kind have yet been made from North-East Land, they may produce some interesting results The only information brought back during the spring was that gained by Nordenskiold as a result of his journey with Palander in 1873 along part of the north coast The first birds to be seen after the winter were some glaucous gulls on March 3, and on April 3 the first snow bunting arrived By the middle of May millions of sea birds had arrived in the fjords and were breeding on the precipitous slopes of the surrounding mountains, notwithstanding that there was no open water in the near neighbourhood The length of time to be spent in North-East Land by the present expedition ought to give every opportunity for comprehensive study of this kind

The remainder of the work will consist of straightforward botanical collecting, and will aim at making as complete an ecological survey as is possible It is hoped, however, that it will be possible to make a detailed investigation of surface markings, and especially of the polygonal markings which appear to be characteristic of arctic and, to a less extent, of Alpine regions Various studies have been made of these, and perhaps of greatest interest in this respect is the work which has been recently carried out by Mr N Polunin It seems to be probable that the causes vary from place to place, and that no generally applicable theory can be framed, the investigations of the growth of the polygons over the year may, however, throw some fresh light on the subject

Weather conditions naturally will control the degree in which the biological programme of the expedition is carried out, although it is much more independent of weather than the survey, for example With a working period of fourteen months, there is ample scope for varied work The expedition expects to return during the late summer of 1936

Cancer and the Theory of Organisers

By C. H WADDINGTON, Christ's College, Cambridge

THE fundamental fact about cancerous tissue is that it has escaped from the normal growth-controlling agents of the body The escape often involves a change in histological type The problems which are raised are clearly connected with those studied in experimental embryology, where again it is the causal mechanism underlying growth and histological change which is under investigation Experimental embryology has recently made important advances, and the time has perhaps come when it would be profitable to consider the way in which the new embryological theories would formulate the well-known problems of cancer research.

The illuminating researches of Spemann[1] provided the beginning of an answer to the outstanding embryological problem of why one part of an egg develops into one organ and another part into a different organ. Spemann showed that in the amphibian gastrula the developmental path followed by any given piece of tissue is defined by its relation to the blastopore region, which was therefore termed the organisation centre. Further research has shown that one facet of the activity

of the organisation centre consists in transmitting a stimulus to the ectoderm which comes to lie above it, causing the latter to develop into the neural plate. This is a two-term reaction, between the stimulus (or evocator[3]), emanating from the organising roof of the primitive gut, and the overlying ectoderm. The ectoderm, it was found, will only react when it is in a reactive, or 'competent'[3], state Very little is known about the nature of competence or how it is acquired, probably changes are proceeding within the cells from the time of fertilisation onwards eventually bringing them into an unstable state, when the evocator-stimulus is able to push them into one developmental path or another The evocator stimulus has been shown to be due (both in the amphibia[4] and in birds[5]) to the presence of a chemical substance, as to the nature of which a great deal of research is being carried on at the present time

The two concepts of evocators and competent tissues can be applied, with some modification, to the consideration of cancer. There is little evidence that the susceptibility of adult tissue to cancer-provoking agents varies in the same way as the competence of embryonic tissue varies with the passage of development, although the fact that cancer is to some extent an old-age disease may be suggestive in this connexion. But as between different individuals, the genetic differences in susceptibility to cancer may be considered as differences of competence in the genetically different tissues Again, changes of competence need not be due to internal causes Thus it has been suggested[6] that the mammary gland must be acted upon by œstrin before it is capable of reacting to the specific lactation hormone One can phrase this either as a case in which œstrin brings about a change in the competence of the mammary gland, or one in which lactation depends on the consecutive action of two evocators In dealing with the facts of the inception of cancer, it may be necessary to envisage similar chains of reactions

Many types of cancer-producing stimuli, or 'cancer-evocators', have been described viruses, specific chemical substances, spontaneous changes in the metabolism of the cells, general irritating agents, etc. Particular interest is attached to the sterol-like substances recently isolated and synthesised by Kennaway, Cook and their collaborators[7] The evocator of the amphibian neural plate probably belongs to the same group of substances[8]. In fact the similarity is so close that one at least of the synthetic carcinogenic substances, namely, 1 : 2 . 5 . 6-dibenzanthracene, is probably capable of acting as an evocator when introduced into the amphibian gastrula[9]. The reciprocal experiment cannot yet be made, as the evocator has not yet been purified Woerdeman[10], some time ago, had the idea that cancer tissue might be able to act as an evocator, and succeeded in confirming the suggestion, but unfortunately it did not occur to him that all adult tissues might have the same capacity, and he made no controls to exclude such a possibility. Later work by Holtfreter[11] and others has shown that this is in fact the case, and it is still unproved that the evocating properties of cancer tissue are any different from those of any other part of the body Holtfreter also made the very important discovery that the newt evocator is present throughout the whole egg, although it is active only in the region of the organisation centre In the remainder of the egg it can be activated by any process which coagulates the cell proteins One immediately searches for some metabolic peculiarity of the organisation centre which might explain the liberation of the active evocator in that region The most striking feature which has been discovered is the extremely rapid disappearance of glycogen[12] The activation of the evocator may not be necessarily connected with this glycogen anabolism, but the facts suggest that interesting comparisons may be possible between the metabolism of the organisation centre and that of tumour tissue

The analysis of development into evocators and competent tissues is only half the story. The organisation centre is not uniform, one part of it stimulates the ectoderm to form the neural plate of a head, while another part induces the formation of the spinal column[13] These regionally different effects cannot be accounted for by the mere presence of one chemical substance, they necessitate the assumption of a regional distribution of one or more active substances within the organisation centre. The processes by which different parts of the centre induce the formation of different definite organs are spoken of as 'individuating actions', and the organisation centre is said to be the centre of an 'individuation field'[3] The main characteristic of an individuation field is that all tissue lying within it tends to be built up into a complete embryo, and in any one part of the field all tissue tends to be built up into the organ corresponding to that part

The individuation field, then, is the agent* which controls the growth of the different parts in a harmonious way so that a normal individual is formed In later life, the individuation field splits up into smaller separate fields, such as leg fields, head fields, etc These are the agents from which cancerous growth has escaped In mammals their effects are normally not very striking, their influence is confined to the control of the minor

* This is a convenient but loose form of expression The field really expresses the formal properties of the distribution of the unknown growth-controlling agents

repair growth of the body, and they are probably capable of very little more than this The adult fields, however, are much more potent in those animals in which regeneration is possible In the newt, for example, the leg field can mould into a limb any mass of competent tissue either grafted into it or formed as a regeneration bud

Possibilities of the experimental testing of the action of powerful individuation fields on cancerous tissue immediately suggest themselves Is there a difference in the susceptibility to cancer between the Urodeles, which have a high capacity for regeneration, and the Anura, which have a low capacity ? If there is, is the difference due to the presence of more potent individuation fields in the Urodeles, or to a greater competence of their tissue for proliferation ? In some animals there are differences in the capacity for regeneration in different organs , one would like to know whether these differences are correlated with differences in the susceptibilities of the organs to cancer, or with the behaviour of tumour tissue transplanted to the various sites

Once the problem of the relation of cancer to the individuation fields has been stated, the methods of attack are legion Some work has already been begun ; cancer tissue is being transplanted into embryonic regions where powerful fields are at work, and the influence of carcinogenic agents on regeneration is being investigated. But the embryological approach to the study of cancer has been stated here in the hope that workers whose experience has brought them into closer contact with the facts of the incidence of cancer may be led to see whether this point of view may not enable valuable conclusions to be drawn from the facts which are already known

Obituary

SIR EDWARD SHARPEY-SCHAFER, F R S

THE death of Sir Edward Sharpey-Schafer at North Berwick on March 29, in his eighty-fifth year, will be greatly regretted all the world over His method of resuscitation of the apparently asphyxiated, for which he was awarded the Distinguished Service Medal of the Royal Life Saving Society in 1909, brought him well-merited fame. Public notices describing the method and placed in conspicuous situations wherever there is danger from death by drowning and gas poisoning, and its use by all first-aid societies and ambulances, have rendered its discoverer the best known of all physiologists so far as the general public is concerned.

Sharpey-Schafer was a genius in the realm of physiological research and teaching. In all his work he was remarkably lucid and arranged his facts in a very interesting and refreshing manner, keeping his lectures alive by frequent reference to the researchers who were responsible for the work under consideration. Both in his discourses and in his writings he fully realised the value of demonstration and used cleverly selected illustrations in abundance. His system of teaching histology serves as a pattern, and his publications in this field include "A Course of Practical Histology", "Essentials of Histology" which has reached its thirteenth edition, and a "Text-Book of Microscopic Anatomy" which forms Part I of Vol 2 of "Quain's Anatomy", of which Sharpey-Schafer was one of the editors For his experimental classes he wrote a concise handbook, "Experimental Physiology".

Sharpey-Schafer was educated at Clewer House School and University College, London, where he gained several scholarships, including the first Sharpey scholarship. He served as assistant professor of physiology from 1874 until 1883 when Burdon-Sanderson was in charge, Sharpey the histologist having resigned in 1874 , in this year Sharpey-Schafer gained the M.R C.S Burdon-Sanderson was appointed to the chair of physiology at Oxford in 1883 and thus Sharpey-Schafer became Jodrell professor at University College, London, in the same year. He occupied this chair until 1899, when he was elected to the chair in the University of Edinburgh. This he retained until 1933, when on his retirement he had completed fifty years of service as a teacher of his science. Thus he came into contact with large numbers of students, scientific and medical, from all parts of the world During the same period he encouraged and trained many researchers and future professors of physiology. He kept an active interest in research right up to his retirement, and amongst his most recent work was an experiment on nerve function which involved an experimental section of a nerve in his arm. His researches brought him the fellowship of the Royal Society in 1878 when he was only twenty-eight years of age. The same society awarded him a Royal Medal in 1902 and its most coveted prize, the Copley Medal, in 1924.

Another field of research in which Sharpey-Schafer was actively engaged concerned the ductless glands and internal secretion. With Oliver he was a pioneer in the investigation of the function of the suprarenal

glands. Swale Vincent, one of his assistants, also played a prominent part in the earlier researches on internal secretion and observed development of immunity to hormones In this field Sharpey-Schafer occupied a leading position and published "The Endocrine Organs", originally founded upon a course of lectures, the Lane Medical Lectures, delivered at Stanford University, California, in the summer of 1913. The first edition of this book was published in 1916 and the second, Part I in 1924 and Part II in 1926. He introduced the term autacoid (αὐτός, self and ἄκος, a medicinal agent) to include those drug-like substances produced by the organs of internal secretion for the purpose either of exciting or of restraining the activity of other organs, for the excitants he kept Starling's original term 'hormones' and for the restraining substances he introduced the term 'chalones'. His other researches and publications were very numerous and covered nearly the whole field of experimental physiology and histology. His early work on the minute structure of the fibre of the wing muscle of insects and his theory of muscular contraction attracted much attention He also investigated ciliary and amœboid movement, the function of the spleen with the plethysmograph, fat absorption by the small intestine, localisation of function in the brain and the tracts of the spinal cord, during his earlier days, the study of pulmonary blood pressure, vagotomy and other nerve section covered later stages of his career

Three publications deserve special mention, namely, the "Advanced Textbook of Physiology", Volume 1 in 1898 and Volume 2 in 1899, to which many of the leading physiologists—including Gaskell, Gotch, Leonard Hill, Gowland Hopkins, Langley, Burdon-Sanderson and Sherrington in Great Britain—contributed and of which Sharpey-Schafer was editor, also the "History of the Physiological Society 1876–1926"; he was the last of the original members and was elected an honorary member of this Society in 1930. Further, he founded the *Quarterly Journal of Experimental Physiology* in 1908 and edited it until his retirement in 1933. Volume 23, 1933, of this journal consisted entirely of original papers written by past and present assistants numbering twenty-nine and was dedicated to himself. He was presented with a bound copy of the volume containing an interleaf with their signatures; to obtain the signatures the interleaf had to travel to South Africa, New Zealand, Canada, America and China. On receipt of this bound volume on December 26, 1934, Sharpey-Schafer wrote: "I have now received the bound copy of the Honour Volume with the signature pages—which have gone round the world—bound in. It is a very handsome book, but I do not treasure it on that account, but for the pleasant memories it recalls." The *Quarterly Journal of Physiology* is now edited by a board of editors assisted by a number of collaborators, and in a foreword to Volume 24, the editorial board paid him the following tribute, that they will endeavour to continue the traditions and to maintain the level established by its founder, Sharpey-Schafer.

He took an active interest in the proceedings of the British Association for the Advancement of Science, serving as its secretary from 1895 until 1900. He was its president in 1912, and in his presidential address created a sensation by suggesting that early living matter had its origin in colloidal slime and that chemico-physical activity was sufficient to explain vital processes without the aid of any special vital force He was knighted in the following year, 1913

Sharpey-Schafer was an honorary fellow of numerous medical societies, and was LL D of the universities of Aberdeen 1897, McGill 1908, St Andrews 1911 and Edinburgh 1933, also D Sc of Trinity College, Dublin 1905, Cambridge 1914, Melbourne 1914, Oxford 1926 and the National University of Ireland 1933; he was also M D of Berne 1910, Groningen 1914, D Sci Méd, Louvain 1930 and Hon F R.C P of Edinburgh 1931 He received also the Baly Medal of the Royal College of Physicians in 1897 In 1923 he was president of the International Physiological Congress and in 1933 president of the Royal Society, Edinburgh, receiving its Neill Medal in 1922

Sharpey-Schafer's father was James William Henry Schäfer of Hamburg and Highgate Sharpey-Schafer married twice, first in 1878, Maud eldest daughter of A W Dixey; she died in 1896 His second wife whom he married in 1900 is Ethel Maud, youngest daughter of J H Roberts, F R.C S. Lady Sharpey-Schafer survives him, as also does a daughter, Miss Sharpey-Schafer He also had two sons, the eldest became a naval officer and the younger was a medical student at Cambridge when the War broke out At this time, 1914, the elder son had retired from the Navy and was engaged in planting in Malaya He left this for War service, at first in connexion with the harbour of Singapore and later with the Home Fleet, in the service of which he lost his life The younger son joined up almost at once for service in France, was reported missing and lost his life very early in the War The elder son had two sons, who survive their grandfather, one is a doctor on the medical staff of University College Hospital, and the younger is a lieutenant in the Navy

While professor at the University of Edinburgh, Sharpey-Schafer resided at North Berwick, at first at 'Marly Knowe'—a fine home occupying a beautiful site on a small hill overlooking the west end of the town and the Firth of Forth. At this home during the summer term he and Lady Sharpey-Schafer graciously entertained members of his staff and numerous undergraduates, arranging all kinds of games from golf on the main links to bowls and tennis on their garden lawn These functions were always greatly enjoyed by all under the kindly guidance of their esteemed professor and his charming lady. Among those associated with him in his early days in Edinburgh were the late T H Milroy (Belfast), John Malcolm (New Zealand), P. T. Herring (St Andrews), the late Sutherland Simpson (New York), F. H A Marshall (Cambridge), John Tait (Montreal), Andrew Hunter (Glasgow), W A. Jolly (Cape Town), H. Pringle (Dublin), J. Lockhead (Gibraltar) and W. Cramer (London). With these and other assistants

he may be said to have founded the Schafer school of physiologists.

Sometimes when the Physiological Society met in Edinburgh, Sharpey-Schafer would complete the scientific business in the morning and then invite all the members to spend the afternoon with his family at 'Marly Knowe', North Berwick. During his later years he resided at 'Park End', North Berwick—a house on the foreshore of the Firth of Forth near the golf course. In 1933 he underwent an internal operation and withstood it exceedingly bravely but later developed pneumonia He apparently recovered somewhat from these trials, and was able to go about again slowly and to entertain his friends with his usual mental acuteness. He resigned his chair in Edinburgh in 1933 and remained at 'Park End' but had intended, sooner or later, to move to the south of England to be nearer other members of his family. However, he never left North Berwick and died near the golf course and the Firth of Forth which he loved so much.

With such large numbers of students in his classes, few of them were able to know the man apart from official duty, and to some Sharpey Schafer appeared rather distant, but all his assistants and research workers were able to appreciate the kindly heart and goodwill which characterised their chief and benefactor In 1922 his past and present assistants, co-workers and research pupils presented him with a portrait plaque and medal; the plaque we understand is now at University College, London. Most of his older students did not know him as Sharpey-Schafer but as Schäfer. He adopted the former name in 1918 to emphasise his indebtedness to Sharpey, who inspired his early work It is impossible for an old assistant to express his feelings adequately for this great scientist and staunch friend

J. A C

WE regret to announce the following deaths

Mr C F Cross, F R S, who was associated with the late Mr. E. J Bevan in the viscose process for the production of artificial silk, on April 15, aged seventy-nine years.

Prof W R Hodgkinson, formerly professor of chemistry and metallurgy at the Ordnance College, Woolwich, an authority on the chemistry of explosives, on April 8, aged eighty-three years.

Mr H R. Kempe, formerly principal technical officer and electrician to the Post Office, and author of the "Engineer's Year Book", on April 10, aged eighty-three years

Dr Albert Mann, of the U S National Museum, Washington, formerly professor of botany in the Ohio Wesleyan University (1895 1900) and in the George Washington University (1907–9), an authority on diatoms, on February 1, aged eighty-one years

News and Views

The Sugar Beet Industry in Great Britain

THE United Kingdom Sugar Industry Inquiry Committee, the report of which (H M S O Cmd 4871) was issued last week, failed to come to a unanimous conclusion on the fundamental issue of whether the beet sugar industry should be carried on with State assistance The subsidy policy which was initiated in 1924 essentially as an experiment has already cost the Exchequer more than forty million pounds, and its extension for the present season will cost more than seven million pounds Mr. Wilfred Greene, the chairman, and Sir Kenneth Lee, in their majority report, conclude that there is no reasonable prospect of the industry being permanently self-supporting The principal value of the industry is as a relief measure to arable farming, but they consider the method extravagant and inequitable. Over the whole period of the subsidy, the cash payments to farmers have only just equalled the cost of assistance. The same acreage of beet could, in fact, have been, and still could be secured as cheaply by paying farmers to grow sugar beet and keep them on the farm for use as they thought fit. The majority is unable to recommend the continuance of State support beyond the maximum rate of duty preference grant to Colonial sugar, and it recognises that this would substantially mean the discontinuance of the beet sugar industry in Great Britain. Compensation to farmers is proposed for three years on an acreage basis.

IN the minority report, Mr Cyril Lloyd emphasises the difficulties of forecasting the trend of future prices, and of giving precise values to the indirect benefits from the industry National considerations of the difference between free trade and protectionist policies are, for him, of much greater importance than the contention that, biologically, sugar cane is more efficient than sugar beet for the production of sugar. He recommends continuing the assistance for a long-term period by a levy on all imported sugar. The reports agree on the broad principles of a reorganisation scheme, should it be decided to continue the industry It is proposed to amalgamate the beet sugar interests, and to control the whole industry by a Permanent Sugar Commission. It is also agreed that any such scheme should provide for a programme of research and education on a scale very much larger than that which has existed up to the present. Valuable educational work has been done locally by the factories' agricultural staffs, county organisers and other educational and research institutes, and, since 1927, about £4,000 a year has been spent by the factories on a national programme of technical experiments and education, including a prize scheme for beet growers. In spite of the very large sums involved in assistance to the industry, no funds whatever have been made available by the State itself for research, and no fundamental research of any kind in sugar beet problems has been initiated.

Rivers Medal, 1934, and North African Studies

THE selection of Miss Gertrude Caton-Thompson for the award of the Rivers Memorial Medal for 1934 by the Council of the Royal Anthropological Institute will be cordially endorsed by all who follow the progress of archæological studies with any degree of close interest. The medal is awarded annually, and was founded to perpetuate the memory of the late Dr. W. H. R. Rivers by recognising work of outstanding merit in any branch of anthropological studies. Miss Caton-Thompson's work as an excavator of archæological sites has covered a varied field in time and space. It has ranged from the earliest prehistoric period to the fringe of historic times in Egypt, the Libyan Desert and southern Africa. Her investigation of the Zimbabwe culture of Southern Rhodesia has not only pricked the bubble of speculation, but it has also based the solution of an obscure problem of African ethnology on an assured body of archæological fact. No one will question that Miss Caton-Thompson's work is "characterised by wide knowledge, sound judgment and insight", to quote the words of Dr. H. S. Harrison in making the presentation of the medal at the meeting of the Royal Anthropological Institute on April 9, at which Miss Caton-Thompson delivered a lecture on the results of the Institute's archæological expedition to the oasis of El Kharga, of which she has been in charge. The importance of these investigations may be gauged from her examination of their bearing on some Stone Age problems of North Africa—problems which recent studies, especially by French archæologists, show to be assuming an increasing importance in the reconsideration of the prehistory of North Africa and its relation to the origin and development of the later palæolithic and mesolithic cultures of Europe (See NATURE, 133, 107; 1934. 134, 975, 1934. 135. 550; 1935. An account of the investigation of the rock-shelter of Afalou in Algeria will appear shortly.)

MISS CATON-THOMPSON'S investigations of geological and archæological conditions at Kharga, which have extended over a period of three years, have fulfilled expectation in throwing much light on the succession of cultures in the early stone age of Egypt and the desert, and have provided material of crucial importance for the problem of early man in North Africa as a whole. They have demonstrated the inseparable relation of the distribution of early man to water supply throughout this region, even where no visible indications of water supply are associated with isolated finds in the desert conditions of to-day. Variation in the quantity and distribution of moisture in quaternary times, as indicated by an examination of the geological conditions at Kharga, affords a chronological criterion in determining the age and succession of stone age cultures. Miss Caton-Thompson indicated the significance of the mound springs in French North Africa, where an Upper Acheulean, with which nothing in Egypt is comparable, shows non-local peculiarities which link with Palestine. In comparing and contrasting the succession of cultures at Kharga from Acheuleo-Levalloisean to neolithic with that of adjacent regions, Miss Caton-Thompson pointed out that M. Vaufrey's views on the dating of the Capsian culture, if fully accepted, force a revision of ideas concerning Aurignacian origins in western Europe and Kenya, and a redating of desert pictographs. Certain gaps in the series might, she thought, be bridged by discoveries in the later Aterian series. On the whole, Miss Caton-Thompson's investigations in the later phases of the Kharga series would appear to support the most recent views of French archæologists on the weight to be given to local development and specialisation rather than to contact and movement.

F. W. Harmer (1835-1923)

APRIL 24, 1835, saw the birth of Frederic William Harmer, one of the pioneers in the field of East Anglian geology, and one of the last of the distinguished amateurs by whom the science was advanced so much during the Victorian era. Harmer came of an old Norfolk family, and by his public services was prominently identified with the city of Norwich. In his early years he had only scanty leisure to devote to geology, but a chance meeting with the younger Searles Wood was the beginning of a long-continued geological partnership. The map they prepared of the glacial deposits of Norfolk and Suffolk on a scale of 1 inch to the mile was the first 'drift' map of the kind in the world. After the publication of much valuable material on the Pleistocene deposits of the east of England, came Wood's death in 1884. For a time, Harmer devoted himself to municipal duties and the politics of the day, but some ten years later, when he might well have felt entitled to the leisure of life, he resumed an intensive study of the Tertiary and Quaternary geology of East Anglia and the Continent. A series of papers on the Crags, still standards for reference and highly esteemed, inaugurated a new regime in East Anglian geology; and his contributions to glaciology and palæo-meteorology were no less stimulating. Two outstanding productions of the eve of his life, each entailing immense labour, were the detailed map showing the types of boulder clay and trails of erratics in England and Wales, and the great monograph, published by the Palæontographical Society, on the Pliocene Mollusca. The latter work was an achievement which will long earn the gratitude of investigators, and will ever remain a fitting monument to his memory. An appreciation of Mr. Harmer's scientific work appeared in NATURE for June 9, 1923 (p. 779). Sir Sidney Harmer, formerly director of the Natural History Departments, British Museum, is a son of Mr. F. W. Harmer.

Franz Chvostek (1834-84)

THIS year marks the centenary of the birth of Franz Chvostek, one of the most eminent Austrian military doctors of the last century. The exact day and month of his birth are not ascertainable. He qualified in 1861, and for the next few years he served as a regimental medical officer. In 1868 he was appointed lecturer in electrotherapy at the

Joseph Academy in Vienna, where he succeeded Duchek as director of the medical clinic in 1871. He held that office until 1874 when he became head of a medical department in the Garrison Hospital, Vienna, and remained there until his death on November 16, 1884 His literary activity is shown by the fact that during the last twenty years of his life he published no less than 163 articles on various medical subjects. Although he specialised in electrotherapy, he published only six papers on the use and value of electricity in medicine, most of his writings being concerned with the pathology and treatment of diseases of the nervous system His name is attached to a sign consisting in the sudden spasm seen on tapping one side of the face

Excavations at Colchester

The preliminary survey, anticipatory to complete publication, of the results of five years excavation on the Romano-British site at Colchester, which Mr Christopher Hawkes contributed to *The Times* of April 12, by bringing together the more significant of the details already reported in the accounts of current progress, gives a clearer conception than has previously been possible of the extent to which this investigation has added to our knowledge of conditions in south-eastern Britain immediately before, and in the early days of Roman conquest. The magnificent system of fortification which has been revealed, in its relation to the occupation site which it defends, bears eloquent testimony to the high degree of organisation and the social and political importance attained by this British town, while the character of the finds, especially the local factory of Samian ware, a feature without known parallel in Britain, indicates, on one side its importance as a centre of British culture, and on the other its standing as a point of close economic, and probably political, relation with the Continent Although it has been possible to follow the course of events on the area of British occupation and its history in later days in some detail, the position still remains somewhat obscure. It would appear as if still more important discoveries have yet to be made. Nothing that appeals as adequate to the dignity of this centre of the Belgic settlers has as yet been discovered. It is all the more important, therefore, that means should not be lacking to follow up the investigation before the commercial development of the area precludes further excavation. The appeal, of the Colchester Excavation Committee for further funds deserves, and should receive, generous support.

Unveiling of the Replica of the *Rocket* Locomotive

On April 11, the Minister of Transport, Mr. L Hore-Belisha, unveiled the new replica of the *Rocket* which has just been added to the locomotive collection in the Science Museum, South Kensington. Mr. Hore-Belisha pointed out that the importance of the *Rocket* in the history of the locomotive lies in the fact that the chief features of its design had been followed down to the present day. He then referred to the precautions for the public safety which have been taken from the earliest days of the railway, so that the numerous regulations which govern the movement of traffic on rails are not regarded as restrictions, but as guarantees of efficiency and security Had similar foresight been shown in connexion with the motor-car, the nation might have been spared the material, economic and personal loss which the weekly casualty lists reveal We are now trying to make good rapidly the omissions of forty years. The measures we are now forced to institute, had they proceeded *pari passu* with the growth in the numbers of mechanically propelled vehicles on the road, would have been regarded as natural. Methods of road traffic control are being borrowed from the railway The *Rocket* demonstrated its capacity in a competition on the railway To-day, it would probably have been sent to the testing station at Vitry, in France, to enable its operation to be scientifically studied In the country which produced the *Rocket*, there is no similar testing station for locomotives, and Mr Hore-Belisha expressed the hope that the omission would be repaired

Liverpool Naturalists' Field Club

On April 27 the Liverpool Naturalists' Field Club celebrates the seventy-fifth anniversary of its foundation by a field meeting at Rabymere, Cheshire, where its first meeting was held in 1860 The Club has been responsible for three floras of Liverpool, one the work of Mr. Robert Brown, who also wrote the botanical section to the British Association Liverpool Handbook, and the last two the works of Col C. T Green. Founded by the Rev H H Higgins (president 1862–93) and Dr Joseph Dickinson (president 1860–62) the Club has maintained an active and amiable co-operation between professional scientific workers and amateurs in all branches of field natural history, and at present has referees in botany (W. S. Laverock), micro-fungi (Dr C. T Green), aquaria (Fred Jefferies), lepidoptera (Mrs Makinson) and ornithology (Eric Hardy), the ornithological section having plans to form a local bird observatory or ringing station like that at Heligoland, as a mark of the anniversary. Some of the leading members in the Club's history were: Rev. H. H Higgins, who discovered 200 additions to the local flora in four years, and was author of works on the fungi, Diptera, flora and other subjects of the Liverpool district, and particularly the notable collection of fern fossils he discovered at Ravenhead, Lancashire, G H. Morton (president 1894), who delivered an address to the Club on the geology of Liverpool which the council published and which was later enlarged into his celebrated "Geology of Liverpool"; Col. J. W. Ellis (president 1899 and 1910) and Prof. Robert Newstead (president 1907–8), entomologists, and Dr. Joseph Dickinson, author of the second "Flora of Liverpool". Since its foundation, the Club has not failed to issue an annual proceedings of 40–50 pages, and at one time its members issued their own monthly journal, the *Liverpool Naturalists' Scrap Book*, followed by the *Liverpool Naturalists' Journal*. The honorary secretary is Mrs. W. S. Laverock, Millbank, Mill Lane, Wallasey.

Jersey Meeting of the British Empire Naturalists' Association

THE decision of the council of the British Empire Naturalists' Association to hold a summer holiday meeting at Jersey in the latter half of June is an interesting tribute to the natural history interests of the Channel Islands, where so many Continental and North African plants reach the northern limit of their distribution, and certain reptiles and birds unknown in England may be studied. In its flora, Jersey holds most interest to the British naturalist for the very mild winters permitting up to forty species to flower in late December, thus producing a Continental rather than British flora. The most interesting species on the island not found in the rest of the British Isles are the Jersey bugloss, the Jersey toadflax, one of the rarest of European flowers blooming at the end of May; the Jersey star thistle, and the loose flowered orchid. The region of St. Ouens Bay is considered the richest botanically, for there are few woods on the island, though such rare flowers elsewhere in Britain as the wild daffodil flourish on the cliffs, maiden hair fern in certain rocks, wild wallflower on the walls of Mont Orgueil Castle, yellow horn poppy, golden samphire, sea-lavender and sea kale on the coast. *Scirpus americanus*, found at St. Ouen's Ponds, is a very rare rush of the Jersey flora, while the Jersey fern (*Gymnogramme leptophylla*, Des.), a North African species, is equally interesting.

FROM the point of view of marine zoology, Jersey offers invaluable opportunities to the visitor. Frequent storms have revealed the stumps of submerged oak and alder forests in St. Ouen's Bay, the Museum of the Société Jersiaise possessing a photograph of some five hundred stumps visible on one occasion. Of bird-life, the island is rich in sea-birds, and a young herring-gull ringed by the London Natural History Society at the colony at Point Grosnez on June 24, 1934, was recovered at St. Nazair (Loire Inf.), France, on November 1. The beautifully marked wall lizard is found on the island, though it does not occur in Britain except as an escaped pet. Similarly, the insect fauna is rich in Continental forms, particularly butterflies, seldom reaching England. Geologically, Jersey resembles France, though in parts it may be likened to South Ireland, Devon and Cornwall. The rocks are mostly granitic. Jersey has the most varied rocks of the Channel Islands, presenting a mixture of metamorphic rocks, conglomerates, and sandstones with syenites and quartzites, while shale and blown sand are also prevalent. Archæologically, the island is noteworthy, and its cromlechs have caused wide interest, especially the large one at Mount Orgueil. The president of the British Empire Naturalists' Association is Mr. Douglas English. The arrangements of the Jersey meeting are in the hands of the honorary secretary of the Jersey branch of the Association, Mr. E. R. Casimir, Font Hill, Woodville Avenue, Jersey.

Rationalisation in Industry and Technical Education

IN his presidential address to the Association of Technical Institutions at the annual general meeting on February 22 and 23, Brig.-General Sir Harold Hartley discussed the question of how far the present trend of industrial development, and particularly the increasing size of industrial units, presents new problems in technical education. Following the rapid progress of both pure and applied science under which co-operative research has been initiated and the processes of the older industries subjected to scientific scrutiny, in addition to the development of entirely new industries, had come the beginnings of rationalisation. The tendency to increase the size of industrial units and to operate on the principles of mass production involves scientific research for the analysis and control of each process. While the disturbance produced by the War was a prime cause of the failure of these methods to raise the standard of living, misuse of opportunities afforded by research could intensify our difficulties. The modern method of production creates a new series of problems involving the co-operation of a team of specialists, and this team work is the characteristic feature of large-scale management. The smooth running of a large-scale unit depends on each of the components engaging intelligently in its task and performing this in proper co-ordination with the rest.

SIR HAROLD HARTLEY suggested that technical institutions can do something to assist those entering industry to understand their functions in relation to others, and in selecting individuals best suited for the various tasks. The extent to which it is possible to give the student a general picture of the industry which he is to enter, its organisation and management, and its relation to other industries requires careful consideration. The relation between the technical and commercial departments and the assistance which statistics afford to management are highly significant to-day, and Sir Harold Hartley urged greater emphasis on cost as opposed to efficiency in the discussion of processes and plant. Finally, he emphasised the importance of a dynamic conception of industry and of co-operation both inside an industry in isolating and solving a problem, and between education and research. The understanding between them must become closer and closer if we are to utilise fully the resources of Nature.

The Droitwich Broadcasting Station

IN a paper read to the Institution of Electrical Engineers on April 11 by N. Ashbridge, H. Bishop and B. N. MacLarty, a description is given of the new radio broadcasting station at Droitwich in Worcestershire. The station contains two transmitters each performing a separate function. One transmitter works on a 'long' broadcasting wavelength in the band 1250–1875 metres and the other on a medium wave-length between 200 and 545 metres. The long-wave transmitter has replaced Daventry 5XX, which worked with a power of about 25 kilowatts. This station was the first broadcasting station in Europe to employ a power in excess of five kilowatts. The other transmitter replaces Daventry 5GB, which was first erected as an experimental transmitter, but afterwards gave the

regional programme service to the Midlands. The present aim of the British Broadcasting Corporation is to supply every potential listener with a service of two distinct programmes. The distribution scheme which is now approaching completion will make one programme available to 98 per cent of the population and the other programme available to 85 per cent By virtue of the length of the wave on which it works, and its aerial power of 150 kilowatts, the new long-wave transmitter at Droitwich gives vastly greater possibilities of 'coverage' than any of the other transmitters in the country, all of which work on medium waves The other Droitwich transmitter covers the densely populated districts in the Midlands The Droitwich site was found to fulfil the requirements for a station of this type The subsoil in the immediate neighbourhood is favourable to the propagation of radio waves. Short high-grade telephone circuits connect it with the nearest studio headquarters It is suitable for building work, and there is plenty of space for the aerial system Lastly there is a trustworthy and ample water supply.

Value of Criticism

PROF. ERWIN SCHRÖDINGER, in an article entitled "Science, Art and Play" (*Philosopher*, 13, No 1), maintains that the present-day spirit which challenges all authority and allows nothing to be immune from criticism, manifests itself in the 'crisis' now existing in most of the sciences Science, at any rate research work, together with art and play, provides an outlet for that surplus store of energy which men usually have to spare after satisfying their primary needs It might be argued that science gives far greater practical benefits than art or play, or that the intellectual joy of the research worker is as nothing to the material value of the results obtained But the advances of applied science, as exemplified in greater facilities for travel and communication, give not only material benefits but also pleasure for their own sake Prof Schrödinger admits that science can rarely give direct joy to the community, but what matters is that the greatest possible number of people should have the opportunity of approach to intellectual pleasures It is not accidental that at the present moment the sciences are being forced to a complete reassessment of values, for the ideas forming the background of the individual sciences are connected with the ideas of the age, and the dominant spirit will accept nothing on authority. This should not be feared, for what is worth preserving preserves itself, and requires no protection.

The Citrus Industry in Jaffa

AN article in the *Fruit, Flower and Vegetable Trades' Journal* of February 16 describes "The Jaffa Citrus Industry". Oranges were introduced to Jaffa in the tenth century; they delighted the eyes of the Crusaders and their opponents. An Egyptian devastated the town and the surrounding country in the fourteenth century, and the orange groves were not re-established until the eighteenth century. Palestine exported nearly 1½ million boxes of oranges before the War; her export trade disappeared during the conflict, but now it has returned and increased. Jaffa is the chief exporter of grape fruit, and second only to Spain in export of oranges Forty-five per cent of the exportable crop is at present controlled by Jews and the rest by Arabs, but when present plantings mature, the Jews will control 65 per cent. The development of overseas markets is difficult, owing to the imposition of tariffs, and to the fact that Palestine is a mandated territory and can demand no reciprocity of trade The Government of Palestine has instituted an inspection service, has established a research station and has created a fund for propaganda Difficulties of transport from Jaffa to the port have still to be overcome, production promises to be increased threefold by 1938 The industry is launching a large scheme of advertisement, in an attempt to cope with this increase in output, and already the consumption of Jaffa oranges in England has increased considerably since the scheme was initiated

Land Utilisation Survey

THE fourth annual report, for 1934, of this Survey shows that great progress has been made Of the field work, only about ten per cent of the total area of Great Britain has still to be done The uncompleted areas are mainly in Sutherland, part of the Southern Uplands, the northern and eastern parts of the West Riding, central and southern Wales, and parts of Wiltshire and Cornwall. In preparation of the six-inch sheets for publication, which entails reduction to a one-inch scale, much progress has also been made Twelve sheets have been published, seven others are in the press and twenty more have been reduced Further progress has been delayed solely by lack of funds For many of the sheets published or in process of publication grants, guarantees or advance orders have been obtained, and the Survey is anxious to obtain further help of this kind The Survey is planning a series of handbooks to accompany the published sheets

Cultivation of Tomatoes

THE imposition of duties on imported tomatoes has naturally stimulated the production of this fruit in Great Britain, although the industry had already assumed large proportions. The home production under glass is estimated at more than 1,140,000 cwt., but even so, this only accounts for less than one third of the total home consumption, imports for 1932 amounting to as much as 2,442,000 cwt. Very considerable knowledge with regard to tomato growing has been obtained at the Cheshunt Research Station, and at the invitation of the Ministry of Agriculture, the director, Dr. Bewley, has prepared a bulletin on the subject which provides growers with a wealth of valuable information (Bull. No. 77, Tomatoes: Cultivation, Diseases and Pests. H.M. Stationery Office. 1*s*. 6*d*. net). Soil treatment before planting, manuring, optimum soil and air temperature during growth are among the aspects of the subject discussed in detail, while recommendations as to the

choice of the best variety, methods of marketing and measures to be adopted for the control of diseases and pests are also supplied. In addition, the construction and heating of glasshouses are considered, and a detailed plan of a low pressure hot water heating apparatus is appended

Cambridge Philosophical Society

THE *Proceedings of the Cambridge Philosophical Society* now appears in a new and more convenient form The number of parts in a volume has been reduced from about seven to four, to be published at the ends of January, April, July and October, but the size of the page has been increased, and the general style and layout have been considerably modified so as to bring the journal more into line with the *Proceedings of the Royal Society* and the *London Mathematical Society* The first issue in this new form contains papers by Prof G H Hardy on "Fourier Kernels", Prof G N Watson on 'Ramanujan's Continued Fraction", and six other papers on pure mathematics As for mathematical physics, M. H L Pryce applies Born's new field theory to a simple special case, A Lees places a new interpretation on Dirac's linear wave equation, H A Bethe discusses the neutrino, and W W Sawyer deals with a point in the separation of heavy hydrogen. The experimental papers include experiments on neutrons by C. H Westcott and T Bjerge, and investigations of downcoming wireless waves by J L Pawsey We regret to notice that the Council has decided not to issue any more parts of the *Transactions* of the Society at present In the past it has contained many researches which were of great value, but too lengthy for the *Proceedings*

Population Growth and Birth-Control

RAPID increase of the population of India has led to a demand for the inception of preventive measures Birth-control there, and also in Great Britain, is, however, criticised by Col C A Gill in a recent somewhat polemical paper (*J Hygiene*, **34**, 502, 1934) According to Col Gill, population in an area ought to be considered not only from the point of view of numbers, but also from the occurrence of irregular changes or 'movements' in the population, which, apart from migration, are largely determined by forces controlling the birth- and death-rates Statistical methods forecasting future population ignore such 'movements' of population, and estimates based upon population-growth curves have proved unreliable, for example, in India, and must be accepted with reserve In a primitive community, prolificity as a means of race survival and an essential factor for progressive evolution is a paramount necessity, and artificial birth-control would constitute racial infanticide. Rural India, it is held, is such a community and is under-populated, and any State action to promote the practice of birth-control there is regarded as being a political crime and a biological blunder. In Great Britain, natural forces are now acting tending to limit increase of population, such as postponement of the average age of marriage and, possibly, a real decline in fertility. Since Nature requires a wide field of selection, nothing should be done to restrict the reservoir from which in the past many have sprung who have contributed greatly to human progress The encouragement of birth-control among the masses, it is argued, is therefore to be regarded as being biologically reprehensible

The Geographical Magazine

A NEW monthly publication has appeared entitled the *Geographical Magazine* (London: *Geographical Magazine*, Ltd, 1s) The first number fulfils the aim of the editor to depict the geographical background of important events, works of construction and conservation, and the conditions in which various peoples are living throughout the world Attention will be given also to exploration, travel in little-known lands and among primitive peoples, and the life of animals in relation to their environment The eight articles include accounts of Abyssinia by Major R E Cheesman, India's North-East Frontier by Capt Kingdon Ward, the routes in the North Syrian desert by Miss C P Grant, the aborigines of Central Australia by Mr B Macgraith, the "Changing Face of Amsterdam" by Mr F R Yerbury The home country is represented by an article on the Lake District by Mr Hugh Walpole and Prof P Abercrombie There are numerous and good illustrations and a small map is given with each article Half the profits made by the magazine are to be devoted to a fund for the promotion of geographical knowledge to be administered by a body of trustees under the chairmanship of the president of the Royal Geographical Society

World Survey

PUBLISHED under the auspices of the World Power Conference, a new monthly periodical entitled *World Survey* has appeared this month (5s. net), its aim being described as that of presenting and analysing world economic trends A special feature is the inclusion of a section recording, by means of index numbers, changes in industrial and agricultural production, wholesale and retail prices, unemployment, production of power and fuel and other statistics relating to transport, finance and world trade. In the first number, the articles cover a wide field, including among other subjects the future development of power-producing industries, the international aspects of public works, and machinery and labour displacement. In a special world economic service section, there are articles dealing with Belgium and the gold standard and with the world rubber situation. It is intended that *World Survey* shall facilitate an international exchange of information and opinion between those engaged in the power and fuel industries and economic experts, so that industrial data can be analysed and related continuously to theoretical work. An international bibliography of new publications relating to power and fuel is also included as a monthly feature

Science Abstracts

THE two volumes of *Science Abstracts* of 1934 have now been issued Each is 7–8 per cent smaller than the corresponding volume of 1933, but the decrease in the number of abstracts is in neither case so great The Physics volume has 1,561 pages, more than 300 of which are devoted to the subject index, the supplementary index of apparatus and instruments and the author index The Electrical Engineering volume has 905 pages, more than 150 of which are occupied by subject index and author index Each volume is indispensable to those who would keep themselves up to date in the field it covers

British Health Resorts

THE British Health Resorts Association has issued a new edition of its official handbook ("British Health Resorts Spa, Seaside, Inland (including New Zealand, South Africa, and Canada)" London J and A Churchill, Ltd 1*s*) The handbook is edited by Dr Fortescue Fox, and contains a foreword by the Minister of Health, Sir Hilton Young, and it is claimed that there is no other publication like it in Great Britain or any other country Authoritative information is given of every health resort in the British Empire, and some useful pages are devoted to winter health resorts in Great Britain The information concerning each resort includes an illustration, and details of climate, the diseases for which it is suitable, and particulars of attractions and accommodation

Announcements

SIR HENRY LYONS has been appointed member and chairman of the Advisory Council of the Science Museum in succession to Sir Richard Glazebrook, who has resigned

ACCORDING to *The Times* of April 12, Mr Martin Lindsay has been awarded the Alexandre de la Roquette Gold Medal by the French Geographical Society for his leadership of the British Trans-Greenland Expedition, 1934

PROF. EMIL ABDERHALDEN, director of the Physiological Institute at Halle, has been elected a foreign member of the Lombardy Society of Medicine, and a corresponding member of the Pontifical Academy of Sciences in Vatican City

THE Committee of the A Chauveau Foundation has recently awarded the prize in veterinary science to M. C Dubois, director of the veterinary services of Gard, for his work on undulant fever in animals

ON April 9, Lady Oppenheimer opened an interesting exhibition of books about trees, collected mainly by certain publishers, under the auspices of the society of "Men of the Trees", and displayed at its headquarters at 10 Victoria St, Westminster, S.W 1. In addition to modern books and pamphlets, many interesting old books have been gathered together, including a fourteenth century MS. of St. Isidore's "Etymologia", a kind of encyclopædia of all knowledge as it was known in the sixth and seventh centuries, including the properties and care of trees

THE Tomarkin Foundation is arranging the seventh International Medical Post-Graduate Congress, under the auspices of the University of Brussels, to be held at Brussels on September 12–19, and at Spa on September 20–October 2. The Congress is officially approved by the General Commissariat of the World Exhibition which will be held in Brussels at the same time. Further particulars can be obtained from the Secretary, Tomarkin Foundation, Faculty of Medicine, 97, rue aux Laines, Brussels

ON April 10, Sir John Gilmour, the Home Secretary, opened the new Metropolitan Police Laboratory for the scientific investigation of crime, which has been established at Hendon The members of the Committee which has been formed to advise on the development of the Laboratory are. Lord Atkin, Lord Dawson of Penn, Lord Trenchard, Sir Russell Scott (Permanent Under-Secretary of State, Home Office), Sir Edwin Deller (Principal of the University of London), Sir Bernard Spilsbury, Sir Frank Smith (Secretary, Department of Scientific and Industrial Research), Sir Robert Robertson (Government Chemist), and Mr Hugh Lett (senior surgeon to the London Hospital)

MESSRS BERNARD QUARITCH, LTD, 11 Grafton Street, W 1, have celebrated this year by issuing an extremely interesting list of five hundred rare and choice books (Cat 500) Among these is a number of early scientific and medical classics and rarities To the bibliophile, this catalogue with its bibliographical detail and its thirty illustrations will make a special appeal, and librarians and collectors with funds at their disposal will find many treasures here to tempt them. Prices range from 15*s* upwards, but it must be realised that this is emphatically not a bargain hunter's catalogue, since the average price of the books offered is nearly £100 each

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—A research assistant to the British Cast Iron Research Association—The Director, 21 St Paul's Square, Birmingham, 3 (April 23) An assistant lecturer in building in the College of Technology, Manchester—The Registrar (May 3) An advisory economist in the Department of Agriculture, University of Leeds—The Registrar (May 7). A professor of obstetrics and gynæcology in the University of Hong Kong—The Secretary, Universities Bureau of the British Empire, 88a, Gower Street, London, W.C.1. Two radio research assistants in the Research Laboratories, G.E.C., Ltd., Wembley, Middlesex—The Director.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 624

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Cosmic Rays from Nova Herculis?

THE appearance of a new star in the constellation of Hercules is of considerable interest not only for the astronomer but also for the physicist W Baade and F Zwicky[1] recently advanced tentatively the hypothesis that cosmic rays are produced in the outburst of super-novæ The few communications[2] on Nova Herculis do not show—so far as they are accessible to us—whether this new star can be classed as of the super-nova type The light emission shows an increase from the date of discovery (December 13) until December 25

W Kolhörster[3] has reported that his measurements between December 22 and 31, 1934, with a double coincidence Geiger-Muller counter indicated an increase of 1·7 per cent during the time when the nova was high above the horizon (9-16 M E T) He said that the detection of this effect by the ionisation method would be more difficult on account of the variations of the barometer effect and the directional uncertainties in ionisation methods Nevertheless, it seemed worth while to investigate if very accurate instruments like our Steinke standard apparatus showed any effect of the appearance of the nova

Two of our Steinke instruments were placed at 2,300 m above sea-level (Hafelekar Observatory), and a third apparatus of the same type stood in Innsbruck, under the roof of the University building (600 m above sea-level). They were kept at constant temperature (15° ± 0 2°) and were permanently screened from local radiations by lead shields of 10 cm. thickness underneath and on the sides. The hourly mean values of ionisation were reduced to the same barometric pressure.

First we compared the average intensities of a series of days before and after the appearance of Nova Herculis. This is necessary on account of the irregular variations of the cosmic radiation ('variations of the second kind'). The results are given in the following table together with the mean errors.

	Hafelekar (2,300 m)		Innsbruck (600 m)
	Instrument No 9 (no lead on top)	Instrument No 3 (surrounded by 10 cm lead)	Instrument No. 8 (surrounded by 10 cm. lead)
December 1-12	4 464 ± 0·006 J	2 804 ± 0 004 J	1 777 ± 0·002 J
December 13-20 and 22	4 465 ± 0 008 J	2 807 ± 0·006 J	1 787 ± 0·003 J
Effect of Nova	+ 0 001 ± 0 010 J	+ 0 003 ± 0 007 J	+ 0 010 ± 0 004 J

We see that a very small increase of ionisation is shown by all three instruments , this effect is, however, well within the limits of the mean errors, with the exception of No. 8, where the increase (0·010 J ± 10 mJ) is twice as great as the mean error If we take the average of the values from December 17 to December 20 (or 22) when the new star approached its maximum brightness, we obtain larger effects, which are (compared with the period December 1-12) + 13, + 10 and + 15 mJ, for No 9, 3 and 8 It must be kept in mind of course that even these effects are of the same order of magnitude as the mean errors

If the increase mentioned is really due to the new star, we should expect to get a relatively larger increase by taking average values not for whole days but for hours when the nova was high above the horizon In the week December 13 to December 20 the nova was at its maximum altitude practically at noon Now we must take into account that, at this time of the day, a maximum of the ionisation has been found to occur[4] A possible effect of the nova naturally would be superposed on this solar noon maximum which, on the Hafelekar, exceeds the night minimum by about + 10 mJ Therefore in order to separate these effects we must compare the difference of ionisation at noon and at night before and after the appearance of the new star

This was done by grouping our observations in three different ways as shown below

Difference of Day and Night Ionisation (in mJ) before and after appearance of Nova Herculis.

	Instrument No 9		Instrument No 3		Instrument No 8	
	Nov 22-Dec. 12	Dec 13-Dec 20	Nov 22-Dec 12	Dec 13-Dec 20	Nov 22-Dec 12	Dec 13-Dec 22
(a) Comparison of mean values 9^h-15^h and 21^h-3^h	+ 18	+ 18	+ 4	+ 11	+ 1	+ 2
(b) Comparison of mean values, 11^h-13^h and 21^h-3^h	+ 19	+ 13	+ 6	+ 9	0	0
(c) Comparison of mean values, 10^h-14^h and 22^h-2^h	+ 17	+ 13	+ 6	+ 6	+ 4	+ 2

The noon maximum is well marked in nearly all cases. An increase of the day-night difference after the appearance of the nova is clearly discernible only in three cases (No 3 *a* and *b*, No 8 *a*) Apparatus No 9 on the Hafelekar, which would also show effects of softer radiations, does not indicate any positive effect of the nova Instrument No 3 shows a slight positive effect in (*a*) and (*b*) Instrument No. 8 (standing in Innsbruck, only 600 metres above sea-level) does not show any decisive effect It must be remembered, though, that all these difference effects whether positive or negative are again within the limits of the possible mean errors, and that these are larger here where the mean values taken were not for the whole day.

It is very unfortunate that our measurements had to be discontinued on December 22, so that no measurements at the time of the maximum brightness of the nova were available. Therefore our results are not quite comparable with those of Kolhörster

From the foregoing results, we can only conclude that it was not possible to prove an effect by the ionisation method in the period December 13–22 due to the appearance of Nova Herculis There are indications of a small increase of ionisation after the appearance of the nova, when mean values of whole days before and after December 13 are taken The effect, if it is real, certainly does not exceed 2 per thousand of the total radiation and does not exceed the limits of the mean errors

[1] W Baade and F Zwicky, *Proc Nat Acad Sci*, 20, 254, 1934
[2] NATURE, 135, 193, Feb 8, 1935 Also K Graff, *Zirkular der Mittelmeerstation der Wiener Universitadsternwarte*, Nr 1, 1935
[3] W Kolhörster, *Z Phys*, 93, 429, Jan 1935
[4] V F Hess, R Steinmaurer and H Graziadei, *Wien Sitz Ber*, IIa, 143, 313, 1934

IN the period July 1934 March 1935, we have registered the intensity of the cosmic radiation with a coincidence apparatus, kept the whole time in the same position The counters were arranged with their horizontal axes vertically one above the other, so that the 'field' of the apparatus was 400 square degrees Nova Herculis was in the field of the apparatus from $16^h 10^m$ until $20^h 0^m$ sidereal time (all time references are to mean sidereal time), in culmination it showed an angle of 1° 38′ 50″ towards the south with the vertical line joining the axes of the counters

The accompanying table contains the experimental data, col. I indicates the mean number of coincidences per hour, while the Nova was in the field of the apparatus ($16^h 30^m - 19^h 30^m$), col II gives similar data during other hours of the day; col III gives the difference between I and II as a percentage of II We give the values for the months August, September, October, that is, before the flaring-up of the Nova, and for November, December and January separately. The data for December are repeated in the third row, because that was the time when the greatest changes were occurring in the luminosity of the star; on November 14 it was a star of magnitude 14, while on December 23 it had reached magnitude 1·5. In the fourth row are the data for February, when 36 cm of lead was placed between the counters

	I $16^h 30^m - 19^h 30^m$	II $20^h 30^m - 15^h 30^m$	III $\frac{I - II}{II} 100$
Aug, Sept, Oct	22 69 ± 0 28	22·04 ± 0 11	2 95 ± 1 36%
Nov, Dec, Jan	30 41 ± 0 35	30 83 ± 0 14	0 26 ± 1 24%
December	31 21 ± 0 61	30 54 ± 0 24	2 19 ± 2 15%
February (36 cm lead)	18 97 ± 0 51	19 01 ± 0 20	−0 21 ± 2 86%

The data show that the intensity increase during the time of culmination of the Nova does not exceed in any case four times the mean error, and even twice the mean error is reached only in the means of August, September, October, before the outburst of the Nova

We can infer from the foregoing that the effect of undeflected or, in comparison with the field of the apparatus, not essentially deflected cosmic rays, coming from Nova Herculis is not appreciable—in any event, not appreciable beside the oscillations due to other effects such as diurnal variation.

Judging our results from December in a most unfavourable manner by assuming that the error of measurement may be as great as three times the mean error, we can conclude that the intensity of cosmic rays coming from Nova Herculis is even in that case only twenty times as great as the intensity observed from an average surface of 1 square degree of the sky Astronomically speaking, if we employ the ratio between the average starlight per square degree and the magnitude of the stars, we conclude that the cosmic ray magnitude of Nova Herculis can in no case exceed 1 6^m

The apparatus was constructed with the assistance of the Széchenyi Scientific Society

A Method of Measuring the Collisional Frequency of Electrons in the Ionosphere

I READ Mr Eckersley's interesting letter[1] concerning the measurement of the collisional frequency of electrons in Region F of the ionosphere, but feel very doubtful whether, as he says, his measurements refer to Region F_1 It seems to me that they must refer to Region F_2, the highest and most densely ionised level of the ionosphere At the time of his measurements (1605 on October 1, 1934), other observations, carried out at the Radio Research Station of the National Physical Laboratory, show that the extraordinary ray critical frequency for Region F_1 was 4·2 mc/sec which is different from the value of 5 mc/sec indicated by Mr Eckersley. Moreover, since the ionisation in Region F_1 exhibits a most regular type of seasonal and diurnal variation, with no abnormalities, it does not seem possible to account for the discrepancy as a local effect observed only at Chelmsford. It must also be pointed out that the formula previously given in a discussion of long-delay echoes for the ionospheric reflection coefficient, used by Mr Eckersley, is an approximate one and its use in connexion with this particular problem does not seem justifiable For the ordinary ray reflection coefficient ρ we have, more accurately,

$$\log \rho = - \frac{\nu}{2c}(P' - P) \quad \ldots \ldots \ldots (1)$$

where P' and P are respectively the group and optical paths of the waves, ν is the electron collisional frequency and c the velocity of light. Since Mr. Eckersley's measurements yield values of P' only, he has neglected entirely the value of P in the above formula, although it is known that P' and P are of the same order of magnitude.

It may therefore be of interest that there is a rigorous method of applying (1) in which the neglect of an important term is avoided. Suppose we make

measurements of ρ and P' for two wireless frequencies f_1 and f_2, we have from (1):

$$f_1 \log \rho_1 - f_2 \log \rho_2 = \frac{\nu}{2c}\left[f_2(P'_2 - P_2) - f_1(P'_1 - P_1)\right] \quad (2)$$

Also we have, generally,

$$P_2 f_2 - P_1 f_1 = \int_{f_1}^{f_2} P' \, df , \quad (3)$$

so that, with a little reduction, there is obtained

$$\frac{\nu}{2c} = \frac{f_1 \log \rho_1 - f_2 \log \rho_2}{\text{area } X} , \quad (4)$$

where the area X is shown in Fig. 1 on the usual (P', f) diagram, From (4)

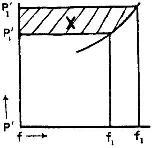

Fig 1

ν can be calculated In differential notation (4) may also be written

$$\frac{\nu}{2c} = \frac{1}{f}\frac{\delta(f \log \rho)}{\delta P'} \quad (5)$$

A further point of interest is that when ν has been found in this way, the value of P, the optical path, may be estimated for any frequency with the aid of (1)

Ramsay and Helium

A story is current in scientific circles which relates to the discovery of helium. It is said that after listening to the lecture on the discovery of argon at the meeting of the Royal Society on January 31, 1895, Mr. H. A Miers (Sir Henry Miers) wrote to Ramsay, directing his attention to Hillebrand's discovery that minerals of the uraninite group gave off nitrogen, when heated with acids The story continues to the effect that Ramsay, being a very energetic man, at once went out and bought up all the clévite that was available, treated the mineral with acid, and got off a gas which proved to be helium. The story is told without malice, and, no doubt, would have amused Ramsay, but, unfortunately, it is true neither of the man nor of the period. The true story is characteristic of both

Ramsay certainly received the letter from Mr. Miers on Friday, February 1, but as he writes in his notebook, he spent that day, and also the following Saturday and Sunday, in revising and typing the paper for the Royal Society The next note in the notebook is "Didn't do much till Friday 15th", when he made and fitted up his first Töpler pump. Actually he had a lot of time to put in at the College, making up arrears of teaching work Then he carried out some additional determinations on the density of argon, purifying the gas specially for the purpose, the results appearing as an addendum to the argon paper This completed one piece of work

Ramsay next turned his attention to some experiments on the direct determination of the specific heat of argon, designed to answer criticisms put forward in the discussion at the Royal Society on January 31 The apparatus was made in the first week in March, and the first experiment was carried out on March 9 About this time his assistant, Mr Donald Matthews, carried out the first experiment on clévite Ramsay noted on March 20 "Matthews had obtained from clévite, about a gram of which I bought from Gregory (88, Fitzroy Square) for 3/6, a quantity of gas by boiling with dilute sulphuric acid". However, this work had been completed during the previous week, for there is a note, later "Crookes got the first lot (Saturday, March 16) but was too busy to examine it all the week" A preliminary examination had, however, been made, for on March 17 Ramsay had written to his friend, Mr Buchanan, "Crookes thinks that the spectrum is new, and I don't see how it can be anything old, except argon, and that it certainly is not We are making some more of it, and in a few days I hope that we shall have enough of it to do a density" The original 3*s* 6*d* worth of clévite had been used up, and a further quantity was purchased

In the meantime, Ramsay continued the experiments on the specific heat of argon, but as no communication was received from Crookes, on the morning of Saturday, March 23, he borrowed a second induction coil and proceeded to compare the spectrum of the new gas, 'crypton', with that of argon "While observing Crookes telegraphed—Crypton is helium, 58749 Come and see it Went and saw it"—so runs the record.

The current story does not accord with the spirit of the man, who could work with amazing rapidity, but who would settle one problem to his own satisfaction before proceeding to the next Nor is it in accord with the spirit of an age, in which the scramble for priority was rather less obvious than at present

A note on the discovery was written the same afternoon and communicated to the meeting of the Royal Society on the following Thursday In those days the Royal Society assumed that the news of a discovery by one of its fellows should first be announced at one of its meetings, if the Society were in session; and in the year 1898 the fact that the discovery of krypton had been communicated simultaneously to the Royal Society and to the Paris Academy, and had become public through the latter body, evoked indignant comments at the meeting at which our paper was read By relinquishing its prerogative the Society has lost a good deal

In a dramatised version of the discovery of helium the departure from fact might be justified, but as a matter of mere history the true story is possibly the more interesting

Early Man in South Africa

I WOULD be glad to be allowed to point out that Dr Leakey's results in Kenya are very closely similar to those found by me on the south coast of Africa—the quartzite area—except in the matter of time.

Leakey's Kanjera skulls are, as stated by Sir Arthur Keith, definitely negroid, in fact to judge merely by his fragments, very closely similar indeed to the man responsible for the Early Mossel Bay industry—of whom I now have three adult (one described by Keith[1]) and one juvenile skulls, that described by Keith, with its boat-shaped frontal region, being very aberrant in this respect This Early Mossel Bay (without a doubt much earlier than the Still Bay and its associated Fish Hock skull) is found in natural strata in the Grey Zone at the base of the Superficial Black layer[2] (also recently found much more numerously in the same zone at Plettenberg Bay by me), and this Black layer, representing present climatic conditions, must be taken to be Holocene

This prehistoric South African (or Kanjera man), however, was not only Holocene In 1934–35 I found sufficient fragments of a Late Stellenbosch skull in a shelter at Plettenberg Bay to convince anyone seeing them that they represent the very same type of man These Late Stellenbosch implements are extremely common in the Red Sand below the Black layer (see also ref 2), that is, in a deposit representing an arid period before the Holocene

If we now assume that the Middle Stellenbosch, at least, is due to the same human race, we at last come to the prehistoric South African more or less contemporaneous with Leakey's Kanjera man Here then we have perfect harmony between South and East Africa, except that Leakey, dealing with massive deposits from large volumes of water, may perhaps be overestimating the age of these deposits

If we now proceed to the lydianite area of the Free State, we find other resemblances—again excepting in the matter of time. A beautifully preserved series of deposits of a streamlet, each carrying implements, is to be seen at Bayswater, Bloemfontein. At a single spot, the following succession is preserved, the whole being more than twenty feet in thickness —

(1) Gravelly blue clay, blue clay, unconformity, representing a period of erosion (drought) during which the recently laid down strata were eroded away.

(2) Red boulder gravel, red grit, red clay, calcareous clay (only preserved towards the downstream end), black clay (only a small piece preserved at the extreme downstream end of the exposure), unconformity.

(3) Red boulder gravel, red grit, red clay, unconformity (at this spot the expected calcareous clay and black clay were completely eroded away)

(4) Reddish sand with its top heavily impregnated with lime—unconformity.

(5) Black layer At this exposure the Layer 3 forms a little hillock so that the Layer 5 has been mostly eroded away.

To my mind, this series can only mean one thing—that the strata represent the remains of five climatic cycles—the same number represented by the sand and peat layers twenty-four miles away at Floris Bad; and from Layer 1 to Layer 4 the lydianite culture was evolving in the same way as is to be seen at the Floris Bad and other sites. It, like the quartzite Stellenbosch, commences as a Clacton-like phase, with large Stellenbosch-like implements in dolerite, but the use of dolorite is almost at once abandoned (except for the production of large horse-hoof shaped cleavers—which are found through all the phases of the culture) and the lydianite flakes pass through Mousterian-like, Aurignacian-like and Magdalenian-like phases, all the phases continuing to be associated with extinct species of mammals The curious point about this evolution of the lydianite culture is that all its phases, especially the earlier ones, remind one (and Mr Van Riet Lowe agrees with me here) of Leakey's Early Kenyan Aurignacian

The early history of South Africa is not therefore as Leakey describes it for Kenya (with a Mousterian-Aurignacian technique following on a Chellean-Acheulean), not as it has been expressed in the accepted classification of South African stone implements, not as it used to be described for Europe—but as Breuil now accepts it for Europe, namely, with a contemporaneous evolution of the Chellean-Acheulean and a Clacton-Mousterian technique The only difference is that, in Europe, one can see no reason for this difference, whereas in South Africa the difference in the available material would to some extent explain it

It is not only in the stratification of natural deposits, and in the mammalian fossils of these, that the extreme age of the lydianite Clacton-Mousterian, as compared with the Late Stellenbosch, is to be seen, but also in the nature of the human remains The latter is associated with Kanjera man (better prehistoric South Africans), the former with the huge, very primitive ancestral form of *H sapiens*[3], which, it may be said in passing, has no points of resemblance, except in size, with the extremely dubious Rhodesian man

Distribution of Nuclear Mechanical Moments

AT present, the nuclear mechanical spins of about fifty atoms, including about sixty isotopes, are known. Of these, the spins of fifty-three odd atomic weight isotopes are known with a fair degree of certainty, some doubt existing only in very few cases. Two types of odd atomic weight atoms exist, namely, those with odd atomic number (A) and those with even atomic number (B) The former possess an odd nuclear proton, the latter an odd nuclear neutron. Amongst the fifty-three fairly reliable spins, thirty-nine belong to the former class and fourteen to the latter. The distributions of the nuclear mechanical moments in the two classes are shown in Fig 1

The difference in the distributions is very striking. No significance is probably to be attached to the missing $\frac{3}{2}$ spin atoms in the lower curve, for as yet only a little more than half of all the atoms of the Periodic Table have been studied. In spite of this, the above distributions appear to have real significance Thus although class B atoms are only one-third as numerous as class A, yet there are more spins of $\frac{1}{2}$ in class B than in class A, and this can scarcely be accidental in view of the general trends of both the curves.

The curves must be bound up with considerations of the building up and stability of atomic nuclei. It is apparent that high values for nuclear moments are very improbable in class B atoms, and class A atoms tend to show that $\frac{3}{2}$ and $\frac{5}{2}$ are very stable values when there is an odd nuclear proton. Tamm and Altschuler[1] have shown that class B atoms sometimes have three neutrons contributing to the total nuclear moment, their spins totalling $\frac{3}{2}$. This spin then combines with an orbital moment to give the

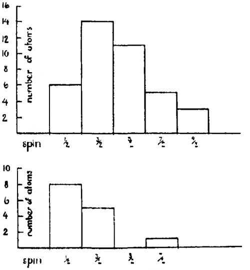

FIG. 1. Distribution of nuclear mechanical moments of odd atomic number atoms (above) and even atomic number atoms (below).

total nuclear mechanical moment of the atom. The lower curve shows that the addition *in parallel* of the neutron spins with higher orbital moments is very improbable. The combination in parallel with a higher orbital moment is obviously still less probable when only one nuclear neutron contributes to the spin.

The Minimum Kinetic Mechanism of Photosynthesis

KINETICS of photosynthesis recently proposed in these columns[1,2,3] fail to account for all temperature coefficients observed, for demonstrable reversibility of the carbon dioxide – chlorophyll complex, and for known or deducible characteristics of the Blackman reaction. The following kinetic mechanism of photosynthesis, supported in every detail elsewhere[4], is proposed as representing the *minimum* number of photochemical and thermal reactions needed to cover the several major facts now established for many chlorophyllous plants in connexion with the following variables: temperature T, light intensity L, concentration of carbon dioxide (CO_2), amount of chlorophyll per unit volume (Chl), concentration of internal Blackman reaction component (E), and specific and indifferent narcotics, intermittent illumination, fluorescence[5] and induction[3]:

dark: $$\mathrm{Chl} + CO_2 \underset{k_2e^{-Q_2/RT}}{\overset{k_1e^{-Q_1/RT}}{\rightleftharpoons}} \textit{Complex} \qquad (I)$$

light: $$\textit{Complex} \underset{k_4e^{-Q_4/RT}}{\overset{k_3L}{\rightleftharpoons}} \textit{Complex} \qquad (II)$$

dark, Blackman reaction: $$\textit{Complex} + E \underset{k_6e^{-Q_6/RT}}{\overset{k_5e^{-Q_5/RT}}{\rightleftharpoons}} \textit{Complex-E} \qquad (III)$$

dark: $$\textit{Complex-E} \xrightarrow{k_7e^{-Q_7/RT}} \mathrm{Chl} + E + \mathrm{Product} \qquad (IV)$$

Photosynthesis is a cyclic process consisting of at least four *experimentally recognisable* forward reactions, besides incidental physical diffusion of carbon dioxide. The scheme given indicates the velocity constants, orders and sequence of the four reactions, and contingent equilibria and steady states. The Blackman reaction occurs *after* the light reaction with respect to a given molecule of carbon dioxide, and involves only combined, not free chlorophyll, and no free carbon dioxide (contrary to mechanisms of Emerson and Green[5] and Conant, Dietz and Kamerling[7]. It consists observably[4] of *two consecutive* reactions. The first is second order and possibly appreciably reversible, the second is first order and irreversible. The over-all Blackman reaction varies experimentally from *apparent first order to zero order*, E reckoned as catalyst. The order decreases as the ratio (*Complex-E*)/(E_{total}) increases with (Chl$_{total}$) (HCN), (CO_2), L, $1/T$, 1/(indifferent narcotic) and growth conditions. Chlorophyll does not act as a simple photosensitiser. It first forms some complex with the substrate carbon dioxide, or a derivative thereof, possibly aqueous, *prior* to the light reaction (not provided by mechanism of Kautsky and Hirsch[8]). Although not always equilibrated, the complex is freely and *measurably reversible*[8] (not provided by kinetics of Baly and Morgan[1] or Emerson and Green[2]). Oxygen appears as product in (IV), but present data do not decide as to elimination of carbohydrate in (I), (III) or (IV). (I) may require an additional reducing component if perchance carbon dioxide is reduced thermally by a mechanism similar to that in chemo-autotropic bacteria prior to the light reaction.

Kinetics derived for the complete mechanism yield an inconvenient quadratic in y, the steady state rate of photosynthesis in the absence of limiting carbon dioxide diffusion. However, the reverse reaction in (II) is normally negligible[8], whence[4,8]

$$y = \frac{k_1k_3L(CO_2)\,(\mathrm{Chl}_{total})}{Dk_3k_1L(CO_2) + k_1(CO_2) + k_3Le^{Q_1/RT} + k_2e^{(Q_1-Q_2)/RT}} \qquad (A)$$

where D, temperature sensitive, is

$$(E)k_5k_7e^{-(Q_5+Q_7)/RT}/((E)k_5e^{-Q_5/RT} + k_6e^{-Q_6/RT} + k_7e^{-Q_7/RT})$$

When the Blackman reaction is apparently first order ($(E) \sim (E_{total})$), equation A is explicit in y, and provides, in accordance with experiment, for hyperbolic relations[8] between y and (CO_2), and y and L; for temperature coefficients independent of (Chl$_{total}$); and for strict linearity of log y in $1/T$ *only* when

any one term in the denominator in equation (A) exclusively dominates, except conditionally the first term. y is temperature sensitive at high L and high (CO_2) due to D; at high L and low (CO_2) due to Q_1; at low L and low (CO_2) only if $Q_1 - Q_2$ is appreciable, and is temperature insensitive at low L and high (CO_2). Q_1 and D appear to vary from organism to organism, and differently, so that the temperature coefficient is sometimes a function of (CO_2) (contrary to conclusion of Baly[3]). The dissociation constant in (I) is about 5×10^{-5} M CO_2 for most plants, and the heat of reaction ($Q_1 - Q_2$) zero in *Chlorella pyrenoidosa*. Specific narcotics normally effect (III)-(IV), indifferent narcotics mostly (I).

Suggestive in connexion with future experimentation, comprehensive but conservative, fairly rigid but capable of flexible, consistent extension, this 'minimum' mechanism may be harmonised, for common points considered, with the well known mechanisms of Willstätter and Stoll, Warburg and Uyesugi, James, van den Honert, Muller, and Emerson and Arnold[9].

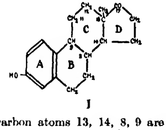
Chemistry of Œstrogenetic Substances

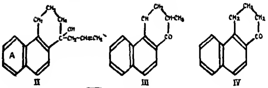
IN œstrin (I) the carbonyl group in 17 is connected with the aromatic ring A through the carbon atoms 13, 12, 11, 9 and through the atoms 13, 14, 8, 9.



I

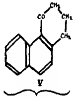
The four carbon atoms 13, 14, 8, 9 are the four centres of asymmetry of œstrin. At the same time, they form the junctions between rings B and C (8, 9) and C and D (13, 14). The orientation in the space of the whole œstrin molecule therefore is due to the arrangement of the four carbon atoms 13, 14, 8, 9.

It is remarkable that, in order to induce œstrogenetic activity, it is not necessary to connect the carbonyl group with the aromatic ring through four carbon atoms orientated in a definite way. A connexion through two carbon atoms is sufficient to produce distinct, although weak, œstrogenetic activity. This result can be deduced from the work of Blum and Bergmann[1] and Cook, Dodds and Hewett[2]. These authors investigated some hydrogenated phenanthrene compounds. In the work of Blum and Bergmann, 1-oxy-1-allyl-1.2.3.4-tetrahydrophenanthrene (II) and 1-keto-2-methyl-1.2.3.4-tetrahydrophenanthrene (III) were active. Cook, Dodds and Hewett got œstrus production with 1-keto-1.2.3.4-tetrahydrophenanthrene (IV), whilst 4-keto-1.2.3.4-tetrahydrophenanthrene (V) was completely inactive:



II III IV

ACTIVE



V

INACTIVE

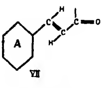
The formulæ II–V compared with œstrin demonstrate that, in order to produce œstrus, the carbonyl group (III, IV) or the corresponding alcoholic group (II) must be connected with ring A through two carbon atoms, as in II, III and IV, whilst the connexion through one carbon atom as in V is insufficient.

Rings B and C of œstrin are connected in the *trans* position, since œstrin is a flat molecule, a flat molecule being possible only if the connexion is of this type. This fact, combined with the results obtained with hydrogenated phenanthrene derivatives, suggested the question as to whether rings B and C are necessary for the synthesis of substances having œstrogenetic properties, and if not, whether fatty-aromatic compounds, in which a carbonyl group is connected with an aromatic ring through two carbon atoms in the *trans* position would to be œstrogenetic.

Substances fulfilling these conditions are easily available. Aromatic aldehydes, combined with pyruvic acid by caustic soda, give unsaturated α-ketonic acids of the general formula (VI)

$$R - CH = CH - CO - COOH \qquad \text{VI}$$

Their connexion with the problem under investigation is shown by the following formulation (VII).



VII

The sodium salts of these unsaturated α ketonic acids can easily be prepared in high purity, as I have shown recently[3,4], and it was found that the aldehydes and pyruvic acid are condensed in these compounds in the *trans* position (M. Reimer[5], E. Friedmann[6]). So far as tested, unsaturated α-ketonic acids, injected into spayed mice, produce œstrus of the same order as 1-keto-1.2.3.4-tetrahydrophenanthrene.

This result can be developed further. Even the aromatic ring, corresponding to ring A of œstrin, is not necessary for the development of the œstrogenetic effect, as the benzene nucleus can be replaced

by the furane ring, fural-pyruvic acid (IX) being even more active than benzal-pyruvic acid (VIII)[5].

$$\underset{\text{VIII}}{C_6H_5-CH=CH-CO-COOH} \qquad \underset{\text{IX}}{C_4H_3O-CH=CH-CO-COOH}$$

Recent experiments suggest the possibility of getting œstrogenetic activity in ring-free compounds by arranging the carbon atoms 13, 14, 8, 9 of œstrin in a suitable way. Work is in progress to see whether these results can be confirmed by the capon-plumage test.

The application of the views developed above for the preparation of cancer-producing substances can easily be seen. Investigations in this direction have been started.

A Gyroscopic Top which will Walk Down Steps

IN his book on "Gyrostatics and Rotational Motion", the late Prof. Andrew Gray explained how a top can be made to move along two parallel horizontal wires when they are rocked so as to change the point of support from one wire to the other. A few years ago, I discovered that a spinning top will automatically walk down two parallel wires arranged as an inclined plane.

While working with high speed motors, it occurred to me that a rapidly spinning top would have a very slow precession and could be made to walk down two wires bent so as to form a succession of steps. The top and steps are shown in Fig. 1.

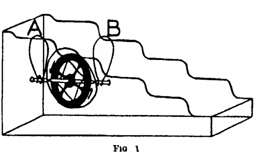

FIG. 1.

My assistant, Mr. Fullmer, who built the top, found that the length of the steps and the height of the risers must be very accurately proportioned to the type of top used. The steps should not form a sharp corner with the risers, but must be curved at each junction.

The top is spun at four to five thousand revolutions per minute and held with one hook in the middle of the highest step while the hook on the opposite side is pressed against the second highest riser (see points A and B in Fig. 1). The top, when released, will walk down the steps.

Infra-Red Photography of Coal

IN a letter in NATURE of February 2 (p. 265) Prof. J. Walton has remarked that infra-red photography of thin sections of coal should give interesting results. We would like to direct attention to some results of work on this subject.

We should mention first that there are already some references to this topic in the literature of coal petrography—for example, Klingner[1], Boddy[2], and Wandless and Macrae[3]. The last-mentioned paper includes a few illustrations of infra-red photographs of coal sections made by one of the present writers.

Besides these examples, however, several hundred other photomicrographs have been taken in this laboratory, and the infra-red plate has proved more generally useful than the panchromatic. Our experience of the two types of plates enables us to make the following generalisations concerning their use in this class of work.

(1) The principal advantage of the infra-red plate will be better understood if we first consider briefly the special photographic problems presented by coal sections. These sections consist of heterogeneous mixtures of substances of the following colours: white (empty spaces), brilliant yellow (spores and cuticles), and a continuous series of shades from pale red through deep red to black (vitrain, fusain, etc.). Obviously it is extremely difficult to make realistic pictures of such objects in black and white, no matter what photographic plate is used. In order to obtain detail in any one of these colours, detail in others must necessarily be sacrificed.

Panchromatic plates, even when the developing and printing process is adjusted to give a 'soft' effect, generally give prints which suggest that the colour transition between pale red and black is less gradual than is actually the case. In infra-red photographs, however, this defect is considerably reduced; hence they generally produce much more realistic pictures.

(2) There are special cases in which the panchromatic is still to be preferred to the infra-red plate; for example, photographs of cell structure in vitrain. In such cases, there may be no yellows and whites to be depicted, the entire field consisting of reds; so, contrary to the usual rule, 'contrasty' prints may be required.

(3) Infra-red plates show another advantage over panchromatics for this work. The field appears to be flattened.

(4) Our laboratory methods for infra-red photography involve the use of the Ilford infra-red plate in conjunction with the deep red filter specified by the plate-makers, and a light source sufficiently intense to enable the image to be focused by eye. Using a weaker light and focusing by computation has not proved a success.

Philosophical Interpretation of Science

IN reviews and articles that have appeared over the name of Prof. Dingle in NATURE, a particular philosophical point of view has been presented as if it were one to which scientific men must necessarily subscribe In his review of Eddington's "New Pathways in Science" in NATURE of March 23, p 451, for example, it is again explicitly stated, and although I am at one with him in many of his criticisms of that book, I am certain I speak not for myself alone when I dissent strongly from Dingle's philosophical outlook on science "We start with experience," he says, "pick out those elements which are common to all observers, represent them by concepts defined in such a way that they relate together as many as possible of the common experiences, and the resulting logical network is the 'external world' "

Now this viewpoint is put forward as if it were a necessary consequence of scientific discovery, indeed we are informed that relativity has saved the man of science from being "forced to admit an external objective world of which his experience was only one aspect" May I suggest that very many men of science assert that science is the result of man's interference in and study of the external world, and that without the latter there would be no science and no men, that they regard the statement that the *logical network* constitutes the *external world* as a fantastic misuse of terms, that when Prof Dingle says "We start with experience" he means "I [H D] start my analysis . . ", that when he talks of "all observers" he is either assuming an external world of which these observers are part or he is still talking of *his* experiences, and he has simply given the rather misleading title of "all observers" to them, that when he uses the English language in writing the review, either he is again using words evolved during the history of an external world and writing them for people all of whom are part of that external world, neither of which has been created out of Prof Dingle's *logical network*, or alternatively *his* mind has built this language and these people out of his experiences, that in the latter event the whole of science, art, literature and philosophy become the organised experience of Prof Dingle himself Does all this not look as if Prof Dingle is trying to pull himself up by his own bootlaces?

Finally, since it is certainly true that a great number of scientific men of philosophical understanding would not accept Prof Dingle's interpretation (itself surely an experience), is he not compelled on his own criteria as to what constitutes the external world to refuse to accord his philosophy any status in that world?

Points from Foregoing Letters

BY pointing his cosmic ray detectors to Nova Herculis, W Kolhorster observed between December 22 and 31 an increase of 1 7 per cent in the amount of cosmic rays and brought this as evidence that cosmic rays are produced during stellar outbursts Prof V F Hess and Dr R Steinmaurer now give figures obtained by a different method showing that in the period December 13 22 a small increase in ionisation due to cosmic rays was recorded (less than 0 2 per cent), an amount within the limits of experimental error Mr J Barnóthy and Mr M Forró, from continuous records with an instrument similar to that of Kolhorster, conclude that cosmic rays coming direct from Nova Herculis were not an appreciable factor in the variations observed during the month of December

Prof E V Appleton gives a new formula for calculating the frequency of collisions between electrons and molecules in the upper atmosphere He points out that the earlier equation recently used by Mr T L Eckersley left out an important factor (the optical path) and that Mr Eckersley's measurements probably refer to the uppermost F_2 region, at about 300 km

The antiquity of the human remains found by Dr Leakey in Kenya has recently been questioned Prof T. F Dreyer directs attention to three adult and one juvenile skull found in South Africa These are closely similar to the Kanjera finds and are considered by Prof Dreyer to be of Holocene (post Pleistocene or recent) age, indirect evidence, from implements, indicates that the South African and Kanjera men already existed in pre-Holocene times Prof Dreyer further believes that the two types of implements (Chellean Acheulean and Mousterian) usually considered to belong to two successive periods (lower and middle Palæolithic respectively) were in fact evolved contemporaneously

The 'spin' of the atomic nuclei is an important factor in determining the probability of disintegration during atomic collisions Dr S Tolansky discusses the relation between the nuclear mechanical moments (due to spin) and the constitution of the nuclei He infers that spin values of 3/2 and 5/2 lead to, or are associated with, greater stability when an odd nuclear proton is present in atoms of odd atomic weight and even atomic number

Three stages have been postulated in the process by which green plants combine the carbon dioxide of the air with water to form carbohydrates Dr D Burk and Mr H Lineweaver claim that at least four reactions can be experimentally recognised They submit a formula showing how temperature, light, concentration of carbon dioxide and of chlorophyll, etc, affect the rate of these reactions

The chemical structure of the female sex hormone, œstrin, and of related synthetic chemical compounds with similar properties, is discussed by Mr E Friedmann He concludes that molecules with œstrogenetic activity, so far prepared, contain the carbonyl (CO) or hydroxyl (OH) group, connected through two carbon atoms with a benzene or other 'ring', other combinations may also be active

Mr J J Walker and Dr L Slater discuss the application of infra-red photography to the examination of thin sections of coal In their opinion the method is useful in giving a more accurate reproduction of the colour transition between pale red and black, and in producing a 'flatter field' Under certain conditions, however, the panchromatic is still to be preferred to the infra-red photographic plate

Research Items

Dating by Beads at Zimbabwe A study of beads in Africa south of the Zambezi by Mr P W Laidler (*Proc Rhodesia Sci Assoc*, **34**, pt 1) aims at a classification of beads, ancient and modern, now or formerly in use among the natives They are divided into ten classes, which are examined in relation, according to chronological considerations, with the stone structure culture of Rhodesia, thus incidentally raising the question of the tenability of Miss G Caton Thompson's dating of the Zimbabwe and associated cultures upon the basis of this class of evidence Viewing the historical evidence, it would appear that no finds have been made which point to contact between South Africa and early Egypt The Arabs landed trade beads on the East African coast previously to A D 1400, but it is impossible to say how much earlier, though Al Masoudi suggests that it was not long before A D 900 Before A D 1500, sites will show Indian beads only, after that date European beads appear in increasing proportion The Rhodesian excavations show three groups, of which Group I is judged to be pre Zimbabwe, but there is little or nothing to distinguish it from Group II, which was regarded by Miss Caton-Thompson as belonging to a later occupation Group I, showing beads with Indian affinities, was regarded by her as a "foundation deposit", pointing to an eighth or ninth century date for the Zimbabwe type of building This ignores in this assemblage of beads one example which is probably of late origin and does not fit in with the historical record It is more probable that it is a 'pre-Zimbabwe' deposit Miss Caton Thompson's dating leaves Class II of the second occupation period with an intervening gap of six hundred years, whereas there is evidence to show that there is continuity of importation as between Class I and II If Group I is, in fact, related to a pre-Zimbabwe culture, it is probable that the foundation date is much later than is suggested by Miss Caton-Thompson

Cultural Origins, Monte Alban, Mexico. It is now practically agreed among archæologists, according to a communication circulated by Science Service, Washington, that the remarkable collection of ornaments of gold and precious or semi-precious stone, which were found in burials on Monte Alban by the Mexican expedition under Dr. Alfonso Caso in 1932, belong to an intrusive culture Four seasons of intensive explorations have produced evidence of structures of a type found elsewhere in Mexico, and going back to a date believed to be contemporary with the Mayan Old Empire culture of Guatemala and Chiapas; but there is nothing to suggest any relation with the treasure find. More than seventy tombs have been explored, but no metal has been found. Recent excavation points to the civilisation of Monte Alban having flourished in A D 300–500, and it would appear possible that it may have been the point of origin of features, architectural and other, which appear on other sites of ancient Mexico Among these is the cross-shaped tomb. An examination of the Dancers' Pyramid, so called from its carved dancing figures, has shown that its interior is a simple stone tomb, rectangular in shape, but with large niches on either side which are virtually the arms of a cross. This appears to be the germ of the idea which blossomed into the huge, mosaic-covered, cross-shaped tomb of Mitla, the site which stands some twenty miles away When the tomb of the Dancers' Pyramid was opened, it was found to contain the skeletons of several individuals in complete disorder Among those scattered remains were five human teeth which had been inlaid with jade, while others were incrusted with hæmatite The pyramid also had three temple bases with sloping stone sides and jutting wall panels Those are found in other parts of Mexico, but nowhere of an earlier date

Man-Eating Sharks A paper by Gilbert Whitley upon Australian shark tragedies shows that not only are attacks frequent, but also they have been increasing in number during the last few decades (*Victorian Naturalist*, Jan 1935, p 195) During the present century, whereas the number of records of attack traced in the ten years from 1912–21 was 13, the number between 1922 and 1931 was 45 and in the three years 1932 34, 16 The increase is probably associated with the more extensive use of shallow waters for bathing In New South Wales, which yields more than forty records or more than half the Australian total, the greater number of shark attacks were made during the months December to April, and this coincides with the most popular bathing season No attack occurred between May and September, although in May and June boats have been bumped or attacked The only safe means of combatting this danger is the building of nets, fences or other enclosures for swimmers On isolated beaches, observations from aeroplanes or from shark towers are said to have proved useful

Pairing and Non-Disjunction of Sex Chromosomes in *Drosophila*. In *Drosophila* females with XXY as sex chromosomes, there have been two views as to how synapsis takes place It is agreed that they synapse in pairs and not in a triad, but Bridges suggested that there is an equal chance of any two of these chromosomes pairing, while Anderson concluded that pairing and crossing over between the X's is independent of the presence of the Y Gershenson (*J Genet.*, **30**, No 1) has obtained further evidence regarding the nature of the pairing and non-disjunction in XXY females by using so called *ClB* stock in which one of the X's has a large inverted section, which reduces crossing over in females heterozygous for the *ClB* chromosome to a very low value He found that the percentage of cross-over X-chromosomes is the same in the gametes of XX females and XXY females in this stock, indicating that synapsis is regularly between the two X's, while the Y goes later to either pole independently In females having the composition XX - ClB, it is found that about 99 per cent of the eggs produced have a non cross-over X Comparison of this frequency with the frequency of non-disjunction indicates that the mechanism of non-disjunction is similar in males and females of *Drosophila*, and is contrary to the hypothesis that regular chromosome pairing and disjunction depends upon chiasma formation

Excretion of Glucose by the Rabbit Kidney. At a meeting of the Royal Irish Academy held on January 28, T Dillon and R O'Donnell described the excretion of glucose by the rabbit kidney The threshold for the excretion of glucose by the kidney was defined as that blood plasma concentration (C_B) above which

glucose is concentrated in the urine Glucose was found to be present in the urine below threshold level, the concentration increasing with the urine rate. Considering the distribution of the threshold values in the experimental animal, the mode of the distribution was 230 mgm per cent, but an individual value may lie in the range 180–420 The threshold level was increased by intravenous injections of sulphate and urea, but remained unchanged after chloride injection It behaved therefore in an analogous manner to the chloride threshold as determined by Conway The important quality of the threshold as above defined is that it is independent of the rate of urine flow The excretion of glucose below the threshold value may be expressed by the equation $K = A\sqrt{(V/T - C_B)}$ where T = threshold, V = urine volume in c c's per minute, and $A = (C_B - C_u)/C_B$, which is closely analogous to the equation derived by Conway for the diffusion of iodine from chloroform to potassium iodide solutions perfused over it, and also to the excretion of chloride below the threshold value The value of K has a coefficient of variation for the individual result of 26, but this variation is independent of the variables used in equation Above the threshold, glucose excretion is expressed by the equation $K_s = \sqrt{V(C_u - C_B)/(C_B - T)}$ The results in this region are obscured by the concomitant high chloride excretion They indicate that glucose and chloride excretion are dealt with by the same kidney mechanism In both cases the 'diffusion-secretion' theory as established by Conway alone accounts for the observed relationships

Hepatics of Southern Japan. Y Horikawa has made an important contribution to bryology entitled "Monographia Hepaticarum Australi-Japonicarum" (*J Sci Hiroshima Univ*, B, Div. 2 (Botany). Tokyo: Maruzen Co, Ltd 2 10 yen) Southern Japan is one of the least-explored regions of the world for the hepaticologist; high mountains (up to 3,962 m), primeval forest and numerous streams are favourable for a rich and abundant hepatic flora. Reports by Stephani (1899–1924) and Okamura (1915–16) record 57 species, this number is reduced to 43, and the author collates later scattered records, including his own discoveries, based on the study of 5,000 gatherings made by himself in twelve visits covering seventy-one days (1930–34). Three hundred and one species, eighty-four genera, twenty-one families and four orders are credited to the region, of which one genus and one hundred and seven species are new to science. The text is in English with diagnoses in Latin, there is a list of Japanese names, the extensive field work and the care given to descriptive matter, illustrations, synonomy,, etc., command attention The conclusion is drawn from phytogeographical data that a land connexion lasted longer on the Japan proper side than on the South China side; the first separation came from the Formosan Channel and later erosion led to the successive separation of the islands of the Liukiu archipelago. Endemism is strongly marked. In the hepatic flora there is an almost total absence of Philippine elements. The presence of many boreal elements proves a former glacial epoch.

Early Daffodil Blooms. An article by Dr J. Grainger (*Gardeners' Chron.*, March 9, 1935) outlines the principles underlying the production of precocious blooms from daffodil bulbs. The period between mid-November and Christmas is usually characterised by a paucity of decorative flowers, and the process described in the article should help to bridge this gap. The young flower of a daffodil is normally formed during the period between lifting in June, until the end of August A rest period then sets in, and usually lasts about six weeks The period of flower bud formation can be hastened by about three weeks if the bulb is kept at a warm temperature (75° F), whilst the rest period is shortened by storage in an ice-box, at a temperature of 40°–45° F. Planting is performed immediately after the low temperature treatment, and the application of suitable growth temperatures results in the production of blooms as early as November 25 The hastening of flower bud formation is the treatment already known as 'preparation' by bulb growers, but in the paper under review, emphasis is laid on the additional need for low temperatures to shorten the rest period.

Antiquarian Study of Fungi. A short paper by Messrs G W Hendry and H N Hansen in *Phytopathology* (24, No 11, 1313–1314, November, 1934) records a novel method of studying the fungi of bygone times The church building of the Mission Nuestra Senora De La Soledad was erected in the Salinas valley of California in 1793–94, and was rebuilt in 1832, from adobe or sun-dried bricks. Wheat straw had been used to bind the clay of which these bricks were made, and it has been found possible to identify remains of *Triticum compactum humboldtii*, Koke in bricks from the ruins The straw also bore evidence of fungal attack, and *Puccinia graminis* and *Ustilago tritici* have been identified These two fungi must have been present in California in 1832, and it is perhaps rather significant that the earliest mycological survey of California (that of Harkness and Moore in 1880) records *P graminis*, but makes no mention of *U. tritici*.

Weed Killers. It has been said that agriculture is a 'controversy with weeds', and weed plants are certainly obstacles to the directive ecology of the gardener Dr M. A. H. Tincker has recently reviewed different types of weed-killers (*J. Roy. Hort. Soc.*, 60, Part 2, pp. 68–79, February 1935). The article deals mainly with chemical methods, although biological means of control are also mentioned. Common salt, petrol, ammonium and ferrous sulphates, carbolic acid, creosote, arsenic compounds, chlorates of sodium and calcium, sulphuric acid, copper sulphate, calcium cyanamide and ammonium thiocyanate are all useful for special purposes, though it would seem that the ideal weed destroyer has still to be discovered. Chlorates are regarded as the most practical weed killers, in spite of the danger of fire Biological methods of control include the provision of vigorous 'smother crops', and the distribution of specific insect pests of weeds Insects are sometimes too discriminating, however, as happened when the cochineal insect was used to control the prickly-pear cactus; it attacked only one species, *Opuntia monocantha*, and further methods had to be used to effect complete eradication.

Coal of the Upper Beeston Seam in West Yorks. Pub. No 35, Physical and Chemical Survey of the National Coal Resources, issued by the Fuel Research Station of the Department of Scientific and Industrial Research (London: H.M. Stationery Office) constitutes Part 1 on the Upper Beeston seam, a highly important

seam in this coalfield, which extends through the Yorkshire, Nottinghamshire and Derbyshire coalfields, forming one complete unit extending continuously for nearly seventy miles in a southerly direction from Leeds It is stated that "For convenience the field has long been arbitrarily divided into three areas, Nottinghamshire and Derbyshire, South Yorkshire, and West Yorkshire The present report deals with the northernmost of these, the West Yorkshire area" The Upper Beeston seam has been the most widely worked in the above area since 1917 A characteristic of this seam consists in a very dull durain, which is a particularly good and clean coal, but hard and usually spoken of as 'hard bands' A large number of samples have been analysed, and the position of these is indicated on a map forming the frontispiece of this volume Upon that map the area of the seam is divided into five parts, in each of which the Upper Beeston seam exhibits a characteristic thickness and structural development, the thicknesses vary from 2 ft 6 in to 4 ft 6 in, the latter containing the dull bands of durain at their maximum development The volume contains a large number of detailed analyses, in which the durain, vitrain, clarain and fusain have been analysed separately, whilst in many cases the calorific power was also determined separately The coal is typically banded throughout, and is shown to contain a number of bands and partings, which in some cases divide the seam into an Upper and Lower part Where this is the case, the Upper part alone appears to be worked

Study of Earthquakes in California Several articles have recently appeared on the study of earthquakes in southern California Mr. H O Wood, to whom we are indebted for the plan of investigation, has described its details and the work carried on in the Seismological Laboratory at Pasadena ("Yearbook of the Carnegie Institution of Washington", 1934, 2347–2353) Dr B Gutenberg has given a full account of this building and its valuable instruments (*Ergebnisse der kosmischen Physik*, 2, 213–237; 1934) Auxiliary stations have also been founded at Riverside, La Jolla, Santa Barbara and Mount Wilson, and at Haiwee and Tinomaha in the Owens Valley, the scene of the great earthquake of 1872 In 1922, Mr. Wood published a map of all the known faults in southern California Soon afterwards, the Wood-Anderson torsion seismometer was devised, and this has proved most useful in the study of local earthquakes More than 200 epicentral tracts have been determined. In most of them, less than a dozen shocks have originated, in others some scores or hundreds, and, in a few, thousands of after-shocks of strong local earthquakes It is interesting to notice that, with one or two exceptions, these epicentral tracts do not cluster along known faults, and that very few of them are connected with the well-known San Andreas fault along which the earthquake of 1906 originated Indeed, the section of this fault between Tejon Pass and Cajon Pass, the seat of the great earthquake of 1857, was almost completely inactive during the six years before 1933.

The Upper Atmosphere. In a paper entitled "Some Facts and Theories about the Upper Atmosphere" by C. K. M. Douglas (*Quart. J. Met. Soc.*, 61, No 258) various observations of pressure and temperature made in recent years in the upper atmosphere with the aid of specially equipped aeroplanes in different parts of Europe are discussed, with special reference to the light that they throw upon the mechanism of anticyclones and cyclones During the year 1932–33, in which many countries co-operated in a special study of the meteorological conditions of polar regions, the so-called Polar Year, a Dutch expedition went to Reykjavik, and upper air data were extended temporarily to Iceland These furnished a good opportunity for studying the changes in a given air mass in the course of one or two days while the air was travelling from Iceland to places in western Europe, where further observations aloft allowed its condition at the end of that journey to be ascertained It was found that the change of temperature of a given air mass for a given height between 2 km and 5 km was often slow, but that rapid rises of temperature, up to 10° F in 24 hours, occasionally took place, apparently as a result of the sinking of initially cold air to a lower level, which resulted in dynamical warming Air which has been warmed in that way may often be identified by its very low relative humidity The author came to regard subsidence of rather less than 1 km a day as an average in an anticyclone that is developing in cold air of polar origin He showed that the air ascending over a rain area is generally warmer than the adjacent air at a height of 4 km Discussing the variations in the height of the tropopause, he comes strongly to the opinion that the air masses just above and below the tropopause move slowly up or down together The parts played by various air movements in the life history of anticyclones and depressions are discussed

Synchronous Time Motors and Accurate Time-keeping. A valuable property in connexion with alternating current motors of the 'synchronous' type is that they keep exactly in step with the frequency of the supply With the advent of the national grid system in Great Britain, which eventually will give time-controlled frequency throughout the whole area, the synchronous motor enables a very satisfactory method of accurate time-keeping to be obtained A paper on this subject by W Holmes and E Grundy was read on March 1 to the Institution of Electrical Engineers The frequency of the supply given by many authorities is time-controlled, and the close relation it bears to standard time is very remarkable Records of the error of a large supply undertaking connected with the grid show that the average errors from the standard time during the day varied between two seconds fast and one second slow Continuity of supply has been observed independently in Cheshire, Lancashire and Yorkshire at private residences having synchronous clocks of the hand starting time. The interruptions occurred about once a year and varied in duration between a few seconds and a few hours. Considering that the tiny little motor rotates at a very high speed and receives no attention this is excellent These motors are rapidly being applied for other purposes wherever accurate time-indicating is required. In the time switches used in electric supply they are rapidly superseding the spring driven clock movement generally used It obviates the necessity for periodical winding and so is economical to supply authorities For laboratory purposes an electric stop watch has been produced embodying a synchronous motor When used on time-controlled frequencies, it will measure short intervals of time with an accuracy up to the twentieth of a second.

Biology and the Nation in Germany

THE administrative appreciation of the biological outlook in national development is nowhere so evident to-day as in Germany and Soviet Russia. A brief account of the current exhibition in Berlin on "Das Wunder des Lebens", which crystallises the use and abuse of biology by the third Reich, may therefore have some general interest. The policy on which it is based was outlined by Dr. Frick, Reichsminister of the Interior, in his inaugural speech on March 23. Unlike the 'liberalistisch-marxistischen' regime, he said, National Socialism views the individual as an inseparable part of the family, and the family as the basis of the nation. The individual therefore has increased duties to the State, but receives in return more rights, more protection, and the immediate promise of a happier and healthier life, secured through education, eugenic legislation and social assistance by the State. It is significant that he did not take a narrow national view of these activities. Indeed, he hoped that the Exhibition would be regarded as a renewed token of international friendship, and expressed the belief that the German people are anxious to work in a spirit of amiable co-operation not only for themselves but also for the growth of a healthy Europe.

Conceived in this spirit, the Exhibition is presented with a freshness and technical excellence which one expects from the organisation behind it—the Deutsches Hygiene Museum at Dresden. It is also noteworthy that it makes no demand on the State budget, advertisers providing the cost and visitors an anticipated profit. Two halls concerned with 'Bekleidung-Schmuck' and 'Ernährung' are entirely devoted to products which not only harmonise with the motif of the Exhibition, but also supplement the technical halls in a most attractive manner. The first and most interesting of these scientific halls deals with 'Die Lehre vom Lebens', and is approached through an impressive 'Ehrenhalle' dominated by a monumental relief (*Empor*) symbolising the release of the German people under the new administration. Among the exhibits, the place of honour is given to 'The Transparent Man', a model under automatic electrical control which illuminates and explains each system of the body in turn. It is a masterpiece of museum technique, enshrined in a darkened chamber in which these words of Augustinus are prominently inscribed:

> "Es bewundern die Menschen das rauschende Meer,
> Die fliessenden Gewässer und den Anblick des
> Himmels,
> Und vergessen über allem Bewundern der Dinge
> Das Wunder, das sie selber sind."

In the main body of this hall, working models and striking diagrams demonstrate the elements of anatomy and physiology in relation to personal and public health. A lattice tower, for example, shows that the daily energy involved in the mechanism of the heart could take two persons to the top of the 'Funkturm' (138 metres high) adjoining the Exhibition. Nearby a large wire cage illustrates the average volume of air (32 cubic metres) required by a man in one day, while neighbouring exhibits indicate respiratory needs during various activities and postures, and the relation between the respiratory and circulatory systems. A square relief conspicuous on the ceiling represents the surface area of the normal number of red blood corpuscles in man. Among the working models, of particular interest are those concerned with the circulation of the blood, the importance of water, the processes of digestion and the time taken to digest various foods, the mechanism and causes of dreams, the cerebral area involved in different actions, the location of bodily pains and the possible diseases they indicate, the functions of the ductless glands and their correlation with abnormalities, and the discrimination of 'basic smells', which visitors may experience for themselves. A small cinema shows biological films ranging from cellular activities to the intelligence of monkeys, while a section for 'Biologische-Leistungsprüfungen' encourages visitors to test their own lung capacity, vocal range, cardiac normality and colour vision.

From this hall one passes over an attractive 'Terrasse-Restauration', with a symbolic fountain, to that which deals with 'Der Träger des Lebens'. An ante-chamber, decorated with impressive reliefs and diagrams of vital statistics in Europe, emphasises the importance attached to a large population of working-class families in the new Germany. In the centre, a 'Glockenturm' rings out the information that nine children are born in Germany every five minutes, while at the base of the structure a huge hour glass records the death of seven persons during the same period. Two quotations from the Chancellor's "Mein Kampf" illustrate the spirit in which this hall is conceived. One is the familiar "Honour the work and honour the worker", while the other sermonises more voluminously as follows: "Auch die Ehe kann nicht Selbstzweck sein, sondern muss dem einen grosseren Ziele, der Vermehrung und Erhaltung der Art und Rasse, dienen". To the right of this chamber is a nursery where the children of visitors can rest and play.

Passing into the main hall, one is confronted with an imposing illuminated exhibit, dominated by the national emblem, showing that National Socialism endeavours to protect every aspect of family life from childhood to old age. Freely translated, the words written over the eagle state that "The hereditary healthy family is the basis of life. The maintenance of their ability to work, and their protection and education in self-help, is therefore one of the great tasks of the NSDAP". And the most confirmed opponent of dictatorship must admit that the new party has attacked that task with commendable energy. One sees in this hall the results of a determined effort for the betterment of the family, through such avenues as education and care of mothers and children, the training of the average girl for her share in the development of the State, and poor-relief measures extending from the provision of food, clothes and coal to travelling schools and clinics which tour the districts. The central organisation for these activities, which cover the entire country, is the *NS-Volkswohlfahrt*, the funds of which are largely obtained from voluntary subscriptions, street collections from the sale of badges made by the rural workers, and so on. In the winter a special effort is made, its success being partly indicated by the fact that nearly 360 million marks were contributed to 'Winterhilfswork' in the winter of 1933–34. The

monthly 'Eintopfgericht' Sunday alone, when a majority of the population contributes to 'winter-help' the savings resulting from restricting the mid-day meal to one dish, provided more than 25 million marks

The next hall, 'Die Erhaltung des Lebens', illustrates the protection of public health in all its aspects, and the visitor can see in it many of the latest devices of preventive and curative medicine, ranging from occupational therapy and radium treatment to the latest Junkers 'Sanitätsflugzeuges' The sanitary and educational activities of the Nazi party are also amply illustrated A feature of the hall is a model marriage consultation centre, to which attention is attracted by illuminated curves, correlated with pictures of social conditions, of the birth- and death-rates since 1820 They show that the birth rate rose from 1820 until 1875, and fell in response to increasing industrialisation between 1875 and 1933, when it again assumed an upward trend The inclination of the death-rate follows, as usual, that of the birth rate The elevation of the birth-rate in the new regime has been secured not only by propaganda but also by State aid, 20 marks a month being given for each child in families of more than three children, provided they are 'racially healthy' It should be added that these consultation centres will increase in importance, for further measures for the betterment of national health are to be introduced very shortly, including legislation for health certificates before marriage.

Special attention is also paid to racial 'purity', Gobineau being given an important niche in the portrait gallery of great men who have influenced the Nazi philosophy In one popular section the Nordic farmer and fighter is glorified in pictures reminiscent of juvenile editions of the "Nibelungensage", surmounted by the statement that "There is nothing more precious on this earth than the seeds of noble blood" On the opposite wall a quotation from "Mein Kampf" stands out in equally bold relief. "Indem ich für die Deutsches Zukunst kämpfe, muss ich kämpfen für die Deutsche Scholle, und muss ich kämpfen für den Deutschen Bauern" In an adjoining section a propagandic pedigree of the Führer' emphasises his association with the peasant class The inevitable Jew-baiting takes the form of a series of 'selected' pictures of Semitic types bearing the sarcastic legend "Der Jude Harry Chaim genannt Heinrich Heine sagt im Buch der Lieder 'Alle Menschen gleich geboren, sind ein adliges Geschlecht'" Alongside are several anti-Semitic cartoons, supported by Herr Hitler's opinion that the Jew can never be a German and that he will always work for the 'Grossere Idee' of his own race The organisers of the Exhibition would have done better if they had refrained from degrading an otherwise excellent scientific exhibition with such propaganda

The Exhibition concludes with a 'Mikrovivarium' and a section entitled 'Wohnung and Siedlung' In the former, living micro-organisms and parasites are projected on a screen and explained by attendant demonstrators In the latter, a series of models illustrates the improvement of housing conditions for the working classes, the central attraction being a full-size example of the suburban houses provided for working men As one leaves the Exhibition, one feels that modern Germany has not only caught something of the spirit of the lines which adorn the cover of this journal, but has also succeeded to an admirable degree in translating it into practice.

I am indebted to the Hon Mrs Ursula Grant Duff and Dr Bruno Gebhard, scientific director of the Exhibition, for many courtesies in connexion with my biological inquiries in Germany

CEDRIC DOVER

Constitution and Properties of Some Non-Ferrous Metals and Alloys

THE spring meeting of the Institute of Metals was held on March 6–7, in the hall of the Institution of Mechanical Engineers.

To all interested in the lead-tin-antimony alloys, and particularly those used for type metals, the paper by Frances D Weaver will be of especial value In addition to the working out of at any rate the main features of this diagram, a considerable amount of data is available concerning the hardness properties of those alloys most commonly employed

Prof. D. Hanson, in collaboration with Mr E J Sandford, has continued his work on the influence of small amounts of other elements on the properties of tin The metals investigated in the present work are aluminium, manganese and bismuth, the results with the first metal being perhaps particularly important in that there is a very definite time effect The greatly improved properties obtained immediately after preparation are not permanent, deterioration of the alloy commences at the skin and spreads slowly inwards and spontaneous cracking takes place. Bismuth also increases the tensile strength of tin very considerably and refines the grain size.

Mr. W. E. Prytherck has examined the mechanical properties of some wrought magnesium alloys, and although no alloys of this metal have yet been produced which respond to heat treatment in the manner which is characteristic of certain well-known aluminium alloys, some of the materials studied have distinctly interesting and promising properties The work which they have carried out over a number of years on the investigation of unsoundness in aluminium alloy castings is continued by Prof Hanson and Mr I G Slater, who have examined the effect of the pressure of the atmosphere under which a metal solidifies They have shown that pressures from fifty to a hundred pounds per square inch are sufficient to remove all visible traces of pin-holes from sand-cast ingots, and that the densities of such castings, particularly those prepared under the higher pressures, are appreciably greater than can be obtained from ingots poured from melts treated by the various de-gassing processes The tensile properties of certain alloys are considerably improved by solidification under pressure, but the fact is noted that in some instances, reheating the casting, by causing the liberation of the gases contained in solution, may give rise to blisters and cavities

The penetration of molten solders into strained non-ferrous metals has been examined by a number of workers. Mr L. J. G. van Ewijk contributes an account of a similar type of cracking in heat-treated nickel-chromium steel The zinc chloride flux is shown to be innocuous, and it is clear from the fracture that the penetration here is of exactly the same order as that which has been found in non-ferrous alloys One of the interesting

features of the work is the considerable difference in the susceptibility to this type of embrittlement to be found in the various nickel chromium steels themselves There is some indication, however, that a high impact value results in a material which is relatively immune Tests carried out on two plain carbon steels suggest that these are not liable to fracture under the conditions of the test Whether, however, this is due merely to the composition of the material, or to the fact that the tensile strengths of these plain carbon steels were distinctly lower than those of the nickel-chromium ones, whence presumably the carbon steel contained less internal stress, is not clear

The effect of five years exposure to urban atmospheric conditions on the strength and electrical resistance of some non ferrous wires is reported on by Mr J C Hudson The work shows that electrical resistance measurements may be used to give a fair idea of the extent to which corrosion proceeds Among the materials investigated copper stands out pre eminently, whilst the most corroded material of all was galvanised iron wire, which rapidly failed once the zinc coating had been corroded away

Dr H J Gough and Mr D G Sopwith give an account of further experiments on atmospheric action in connexion with fatigue The results of the tests on copper and brass suggest strongly that the acid and alkaline impurities present in the atmosphere can have little, if any, influence on atmospheric corrosion fatigue, and that oxygen in the presence of moisture is probably primarily responsible The results of the tests on oxygen-containing and deoxidised coppers show that the comparative behaviour of these materials, when tested in air and in a partial vacuum, is unaffected by the different compositions of the dissolved gases present. Corrosion fatigue, in this instance of duralumin, is also the subject of the paper by Messrs I J Gerard and H Sutton, who show that coatings of organic resins and enamels afford a very high degree of protection, especially when the metal had previously been subjected to the anodic treatment The best results were obtained with a coating of synthetic resin varnish stoved for two hours at 150° C, metal so treated giving a fatigue limit of plus or minus 12·2 tons per square inch for ten million reversals

Other papers were concerned with the reduction by hydrogen of stannic oxide in high conductivity copper, by Dr Alkins and Mr A P C Hallowes, the spectrographic analysis of aluminium and a consideration of certain phases in the silver-cadmium alloys F. C. T.

Science News a Century Ago

Shipping Statistics for 1834

On April 20, 1835, Lieut.-Col. Sykes communicated to the Statistical Society an appendix to his paper on "The Increase of Wealth and Expenditure in the Various Classes of Society". In this he gave particulars of shipping and trade from January 5, 1834 until January 5, 1835 The increase in this period in the number of British vessels employed in foreign commerce, he said, was 689 ships of 108,562 tons burthen, value £1,411,356. The net receipts in the Customs duties had risen from £17,577,549 to £19,931,687. In the year there cleared inwards 11,678 British vessels employed in the foreign trade of a burthen of 2,108,492 tons, which at £12 a ton represented a capital embarked of £25,301,904 The increase in the declared value of exports of the British and Irish manufacturers was £2,052,542, the total amount for the year being £36,541,926. The surplus disposable balance of the public revenue for the year ending January 5, 1835 was £1,608,155 after payment of all charges

Meteorological Observations by Sir John Herschel

The *Athenæum* of April 25, 1835, contained a long abstract from a letter from Sir John Herschel at the Cape, to J Hudson, late assistant secretary to the Royal Society The letter dealt mainly with meteorology, and in it Herschel said that the South African Literary and Philosophical Institution had appointed a Meteorological Committee and had passed a resolution that "On four fixed days in each year, 21st of March, 21st of June, 21st of September and 21st of December we undertake to make horary observations of the barometer, wet and dry thermometer, clouds, wind, meteors, etc etc at the commencement of each hour (per clock) mean time at the place for thirty six hours, beginning at six o'clock in the morning of the 21st and ending at six o'clock in the evening of the 22nd Thus a complete twenty four hours is sure to be embraced in corresponding, or at least, interpolable observations for all *longitudes*" Speaking of his measures with his actinometer, Herschel said, "The following may give you some notion of the purity of our sky and the force of our sunshine.

Effect observed here the day before yesterday 48°75
Usual effect of ordinary good sunshine in England 25°30

I find this instrument extremely sure and uniform in its indications, and having now had nearly eleven years' experience of it, I can safely say that it is perfectly adapted to the purpose. For this reason I shall draw up and forward to the Royal Society, very shortly an account of its construction and use"

Death of Capt. Henry Kater

On April 26, 1835, Capt Henry Kater died in London Born at Bristol on April 16, 1777, he came of a family of German extraction. At first he studied law, but at his father's death in 1794 he joined the Army as an ensign and sailed for India. There he came under Lambton's notice, and was employed on geodetical work After a few years work in various parts of India, ill-health drove him home, and after further service in England in 1814 he was placed on half-pay and henceforth devoted himself to science

Kater was best known for his geodetical work. His memoirs in the *Philosophical Transactions* from 1813 until 1828 refer mainly to the accurate construction and use of the pendulum, the balance and astronomical instruments He applied Huygens's principle of the reciprocity of the centres of oscillation and suspension of pendulums; in 1818 ascertained accurately the length of the seconds pendulum in London, and during 1821–23 was associated with Arago, Mathieu and Colby in the determination of the difference of longitude between Paris and Greenwich. He compared the standard weights and measures of France, England and Russia, and also constructed various standards for Russia. Elected fellow of the Royal Society in 1815, he was awarded the Copley Medal in 1817 for his experiments on pendulums, and from November 1827 until November 1830 was treasurer to the Royal Society.

Societies and Academies

DUBLIN

Royal Dublin Society, March 26 W. HUGHES: Investigations on the control of seedling disease of sugar beet A trial was made of the effectiveness against the blackleg disease of sugar beet, of the bulk seed treatment carried out by the Continental producers, in comparison with treatment with various disinfectants in small lots before sowing and with no treatment A germination test indicated that in the bulk seed treatment some injury was caused by too long contact between seed and disinfectant In a randomised field experiment, the following materials used before sowing gave a significant increase in establishment of seedlings over the control- Germisan and Ceresan (U T 1875 A), 27 6 per cent, Granosan, 25·6 per cent, and Ceresan (old), 21 7 per cent The remaining five treatments, which included the seed producers' treatment in bulk, were not significantly better than the control Seed treatment is recommended as a necessary insurance E T S WALTON Artificial radioactivity

The Dyestuffs Industry and its Lessons

THE story of the dyestuffs industry has often been told, at least in part Few accounts have been more vivid than that given by Mr C J T Cronshaw, managing director of the Dyestuffs Group, Imperial Chemical Industries, Ltd , in his Jubilee Memorial Lecture of the Society of Chemical Industry No such glimpse of the industry from inside has been vouchsafed us since Mr James Morton gave us the story of Caledon Jade Green and later of Caledon Brown Mr Cronshaw's lecture, however, was far more than mere recapitulation He succeeded not merely in revealing some of the difficulties and problems which the industry presents to those engaged in it, but also its ever-changing aspects and its intricate and intimate relations with other industries

It would be difficult to find an industry more essentially dynamic than that of dyestuffs Its very success in ousting the natural colouring matters proved but the prelude to adventure The wider range of shades, the greater brilliance and enhanced fastness of the synthetic colours led to more and more searching demands Not merely textiles but almost every other material in common use has come to the industry with its demands for colour, and the newer industries, like the rayon industry have often made but halting progress until those demands were met Despite its vicissitudes, despite the long struggle for mere existence, the British industry has an honourable share of the outstanding advances to its credit, and those in the post-War period are not unworthy of comparison with the discoveries from which the industry took its birth

The career of the late Dr Duisberg in itself gives some clue to the astonishing fecundity of the industry An impressive feature of the brilliant discoveries of this great industrialist is their close connexion with the most recent advances of his day in organic chemistry Equally significant is the illustration his discovery of phenacetin affords of the relation between the dyestuffs industry and other branches of the organic industry When all allowance is made for the stimulus provided by the discovery of the therapeutic properties of acetanilide, Duisberg and Hinsberg really commenced their research through the necessity of finding an outlet for the *p*-nitrophenol which was accumulating at an alarming rate as a result of the very success of the manufacture of the benzopurpurins.

The discovery which first led the Bayer Co. into the field for which it has since become world famous has been repeated again and again in its essential features It is the very intimacy of the links between the dyestuffs industry and other industries which makes possible the astonishing versatility of the chemist in this industry and the immense range of products which he can provide Unless his intermediate products and by-products found outlet in other industries as vulcanisation accelerators for rubber, antioxidants for rubber or oils and fats, preservatives for wood and other materials, as gum inhibitors, for the control of insect pests and animal or plant diseases, in the manufacture of fine chemicals, pharmaceutical products, and synthetic resins, as softeners, solvents and the like for lacquers and varnishes, finishing agents of all kinds for the leather and textile agents, the resources of the industry would be severely limited by the dead weight of waste products which it would be compelled to carry

Under modern conditions, this factor is even more important The growing demand of the colour-using industries for novelties for specific purposes could scarcely be met in the range required or at an acceptable price but for the way in which intermediate products and by-products can be used for many different and unrelated purposes Nor are the relations static The reaction of the synthesis of indigo on the manufacture of indigo, and its influence on the displacement of the Weldon and Deacon processes for chlorine by the electrolytic process, are paralleled again and again within the dyestuffs industry as in its relations with other industries For example, the introduction of sulphonated fatty alcohols as detergents has given an impetus to the use of fatty compounds for other purposes including dyestuffs, and the dyestuff chemist is no longer content to restrict himself to the use of methyl, ethyl and even butyl alcohol The delicate balance between by-product and main product, the utilisation of waste materials, the competition of raw materials and alternative routes, is proceeding almost as freely to-day over the field of aliphatic chemistry as in the past it has done in the aromatic field.

The existence of such complex relations makes it easy to understand why a man like Dr. Duisberg could find intense satisfaction in the leadership of such an industry despite the brilliancy of his earlier scientific work He at least could never be said to have left the field, and his career seems to underline the argument advanced by Mr Cronshaw in support of the view that the chief factor in the decline of the industry in Great Britain—a decline which no one noticed at the time—was lack of foresight on the part of the originators of the industry themselves

The facts speak for themselves Perkin was a rich man when he retired in 1874 at the age of thirty-six Nicholson retired six years earlier when forty-one, also wealthy, and though Greville Williams remained until 1877 he was then only forty-eight On the face of it the very success of the industry was its undoing There were no long years of drudgery and inadequate reward The industry prospered from the start, and the dyeing trade received the new products well The future prospects were equally bright The textile industries were peculiarly ready for the exploitation of the new dyes The cotton and wool trades were both on the threshold of great expansion, while Mansfield's isolation of benzene from coal tar had provided the industry with unlimited raw material on its doorstep.

Perkin, in fact, could scarcely have made his discovery at a more appropriate or auspicious time, and the explanations advanced of his withdrawal from the industry are unconvincing He at least recognised that the dyestuffs industry was founded on scientific discovery and developed side by side with it None the less he did not see that the greatest service he could have rendered to research in Great Britain was to retain the leadership of the industry he had brought into being, instead, the leading technologist of his day turned his back on the industry at an age when his powers of leadership should have been ripening, alike in the consolidation of results achieved and in the inspiring of other workers with his own enthusiasm

In the light of to-day, it seems incredible that at a time when organic chemistry was still young and vigorous, and when the science as we know it to-day was rapidly taking shape on the foundations laid by Kekulé's theory, a mind such as Perkin's should have turned away from this field. The history of the next decade alone sufficiently endorses Mr. Cronshaw's words: "the industry languished because the pioneer spirit and the creative instinct which brought it into being abandoned it too early, little knowing that what they had accomplished was the merest scratch on the surface. There remained whole new worlds to conquer". Other factors there were undoubtedly,

but the charge of lack of foresight appears to be only too well founded

Without foresight, neither in pure nor in applied science does Nature readily yield her secrets, and success in the dyestuffs industry has always depended largely on the receptivity of ideas and the creative powers which are associated with vision. The displacement of the natural colouring matters merely intensified the struggle for the survival of the fittest among the synthetic dyes themselves. In the marketing to-day of products designed to meet more and more the demands of the user in regard to shade, the fabric or purpose for which the colour is required, the conditions of fastness, the method of application and other factors, the industry depends more than ever upon the exercise of just those qualities which are inherent in all enduring scientific work Indeed, in any scientific industry to-day success depends upon the continuous application alike in the laboratory, in the works or in the management of the assiduous search for facts, the eternal vigilance and the creative instinct and vision which are of the spirit of science itself

Reviews

Relativity and Cosmogony

Relativity, Gravitation and World-Structure By Prof E A Milne (The International Series of Monographs on Physics) Pp x+365+4 plates (Oxford Clarendon Press, London Oxford University Press, 1935) 25s net

IN 1932, Prof E A Milne pointed out that, if the galaxies were initially concentrated in a small volume, those with highest speeds would by now have reached the greatest distances, we might in this way account for the well-known observational result that their radial velocities are approximately proportional to their distances This idea has grown in less than three years into the large treatise now before us The original idea is almost lost in the subsequent accretions, but the spirit of it remains The outlook throughout the book is that the cosmological problem is primarily a matter of kinematics Dynamics, wherever it appears, is treated as the servant of kinematics

A review of the book must necessarily be a review of the theory that it promulgates It is characteristic of modern researches on world-structure that the same physical theory is often expressed in many variant forms, both mathematical and conceptual A confusion of tongues has descended on those who would build a tower whose top may reach unto heaven! On opening Milne's book, it is soon apparent that we shall be asked to learn a new language, but it is not so clear that the language is going to be used to describe a new world. Most of his critics have occupied themselves with the question, not whether Milne's theory is right, but whether it differs from current relativity cosmology. On this point the book is not so helpful as it might have been. Making all allowance for the author's natural desire to present his theory in his own way uncontaminated by conceptions or terminology which he dislikes, we think it is hard on the reader that he should be kept waiting until §463 to learn whether the Milne universe differs from the ordinary 'expanding universe', or whether it is the same universe described in another way When at last we are shown that there is a definite observable difference, we are left mystified as to how the difference has arisen

A 'cosmological principle' is placed in the forefront of the discussion, namely, that a number of equivalent observers arrive at the same description of the universe relatively to themselves—not only of its laws, but also of its actual material contents Milne explains that this principle is merely a specification of the particular system which he has chosen to investigate, and is not supposed to be a law of Nature To use the term 'principle' in this way seems unfortunate When later he finds, in the system so specified, particles the properties of which are like those of cosmic rays, we congratulate him on the happy resemblance of his selected model to the actual universe But we fail to see that he has in any way accounted for cosmic rays. The particles occur in his model because, in specifying his model, he put them there That he did so undesignedly does not affect the question

For the determination of location in space and time, the only means of exploration permitted is interchange of light-signals Milne will not allow his observers to transport scales or clocks He argues that observers elsewhere could not be provided with "rigid-length scales, copies of our own, because we could not say *a priori* what we meant by their being copies". I do not think the National Physical Laboratory would have any difficulty in issuing instructions by which an observer, say, in the Andromeda Nebula, could construct a standard metre; and I do not see the force of Milne's objection to determining lengths in all parts of the universe in this way To exclude such methods

has the drawback that it divorces a great part of practical physics from the theory When I visit the Cavendish Laboratory, I do not find its occupants engaged in flashing light-signals at each other, but I find practically everyone employing rigid scales or their equivalent Sooner or later, the theory must face the task of identifying the significance of these rigid-scale measurements in terms of its symbols, otherwise the greater part of experimental physics will be outside its purview

It is well known that when the means of exploration is confined to light-signals, we reach Weyl's theory in its original form with entirely indeterminate gauge Our first impression was that this might be the origin of Milne's departure from current theory—that he had adopted a different gauge system, having disallowed the rigid-scale measurements which would have refuted it But by p 34 Milne seems to have returned to orthodoxy, and the physicist's favourite transportable clock, namely, the atom, is being freely used If we may "make an immediate recognition" that two carbon atoms are identical clocks, why may we not make an immediate recognition that the grating spaces of two diamonds are identical standards of length ?

Milne's system of particles forms a spherical expanding universe and agrees in this respect with the systems studied, by Friedman and Lemaître But there is a difference in the law of motion, so that a particle in Milne's system does not follow a geodesic So far as I can make out, the difference has arisen in the following way In the Lemaître model, observers who are at rest in the spherical co-ordinate system would give a precisely similar description of the universe and are therefore "equivalent observers" in Milne's sense, but, owing to the accelerated expansion of the universe, they are accelerated away from one another as judged by the Doppler effect Milne, on the other hand, postulates that his equivalent observers shall be in uniform relative motion as judged by the Doppler effect, his universe must therefore have a constant, instead of an accelerated, rate of expansion He has accordingly changed the law of gravitation so as to give a uniform expansion.

There is a passage in the book (§69) which suggests that it is only the analytical difficulty which has prevented Milne from considering equivalent observers with accelerated motion If the uniformity of the expansion is not an essential part of the theory, it follows that his alteration of the accepted law of gravitation is not an essential part of the theory. Perhaps therefore when he has extended the theory in a way which he seems to be already contemplating, we may yet celebrate the return of Prof Milne to the folds of orthodoxy.

A. S. E.

A History of Civilisations

A Study of History By Prof Arnold J Toynbee (Issued under the auspices of the Royal Institute of International Affairs) Vol 1 Pp xvi+476 21s net Vol 2 Pp vii+452 21s net Vol 3 Pp vi+552 21s net (London Oxford University Press, 1934) 3 vols, 52s 6d net

SINCE it is commonly agreed that western civilisation has now reached a supreme crisis in its history, since disillusionment, rife among laymen and men of science alike, is poisoning the well-springs of the spirit, and since the most passionate desire of men of goodwill is to discover means of overcoming our present difficulties, any book which can help us to get our bearings and to see our problems in true perspective must command much closer attention than in easier times Prof Toynbee's superb and philosophic "Study of History", of which the present volumes are the first section, is such a book

The plan of the whole work has been conceived on a grand scale Regarding civilisations, like other manifestations of life, as entities which must be born, which may grow, and which, pending an evolution not yet completed, are doomed to die, Prof Toynbee has taken the life-histories of civilisations present and past as the objects of his study His book will therefore examine the circumstances of their genesis and growths, their breakdowns and disintegrations It will investigate certain major phenomena in their history universal churches, the centres of the spiritual travail which accompanies the downfall and precedes the birth of most civilisations, universal States, the receptacles into which civilisation's earlier and smaller political articulations are usually poured before the end, 'heroic ages', the temporal no-man's lands between related civilisations, through which the outer barbarians of the time, loosed for a while from their established anchorage, wander during the throes of social decay and birth It will explore the contacts of civilisations in space and their contacts and rhythms through time. All this analysis will then be focused on the present outlook of Western civilisation—doubtless with the object of offering our troubled age such guidance as history can give those whose capacity for learning from the experience of others is not blunted by their own preoccupations, and the book will finally close with a survey of the inspirations of historians.

The present volumes do not cover the whole of this immense ground, but are limited to finding civilisations for comparative study, establishing their suitability for this purpose, and examining

the conditions of their birth and growth The developed civilisations, about which enough is known for Prof Toynbee's purpose, number about a score They include Western civilisation and its living contemporaries—the Orthodox Christian, Islamic, Hindu and Far Eastern civilisations, and, among earlier examples, the Hellenic (or Greco-Roman), Sumeric and Egyptiac civilisations in the Old World and the Mayan and Andean civilisations in the New World In Prof Toynbee's view, these ten civilised societies, together with ten or twelve more which the "Study" describes in some detail, are neither links in a continuous chain nor cells in a single growing tissue, but separate entities, each with a life of its own

On this assumption, some twenty cases of birth and successful growth have to be explained Usually the genesis and development of civilisations (in the plural) or civilisation (in the singular) are attributed to environment or racial superiority Prof Toynbee, in a closely reasoned and impressive argument, rejects both alternatives His own explanation is hard doctrine In his view, neither the birth nor the subsequent growth of a civilisation can be accounted for on the flattering assumption of racial superiority or by the quasi-automatic operation of environment On the contrary, both genesis and development are the outcome of a stern and difficult relationship between men and their surroundings, and examples of abortive and arrested civilisations clearly show that this relationship, which he calls "Challenge-and-Response", by no means necessarily or inevitably produces birth or growth

The conception of challenge-and-response is simple in essence and complex in its working out Changing circumstances, Prof Toynbee argues, confront societies, like individuals, with problems for solution, these problems constitute challenges, and out of the effort and suffering which response to them entails, civilisations are born and grow In the case of the earliest civilisations which emerged from the primitive societies that were their forerunners, the challenges were mainly external and material, in the case of later civilisations affiliated to predecessors already civilised, the challenges have been mainly internal and spiritual If either challenge or response is too easy, only a poor civilisation or none at all will result. If, at the other extreme, a challenge is overwhelmingly severe, though a tremendous effort at response may sometimes bring a civilisation to bud, it will neither flower nor bear fruit. But provided that the limits of capacity are not overstepped, the more severe a challenge and the greater the effort required to respond to it adequately, the richer will be the spiritual quality of the resultant civilisation.

Growth is a continuation of the same process It is to be measured not in terms of material expansion or technical advance, but in terms of spiritual development and the transfer of the field of action from outward and material problems to inward and spiritual concerns A growing civilisation is in unstable and not stable equilibrium, the instability resulting from the very fact that a successful solution to any problem by virtue of its sheer success in time causes fresh problems to emerge, until at last, if solutions are no longer achieved, breakdown begins

The process of challenge-and-response, as analysed by Prof Toynbee, works through the individual members of a changing creative minority, who must first spiritually withdraw for a time from active social life while the mystery of creation takes place in their own soul, and who, if they are to be socially effective, must then return to the far more formidable task of converting the majority of their fellows to understanding and effort That so complex and difficult a process should sometimes succeed and sometimes fail is not surprising But it is an advantage of Prof Toynbee's analysis that it eliminates hocus-pocus and conceit from attempts to explain the birth and growth of civilisations and places responsibility for their development on the shoulders of the individuals from whom alone initiative can finally come

So much for the inadequate summary which is all that can be given in a review limited in length to about a word for each of Prof Toynbee's fifteen hundred pages A subject so large, treated on a canvas so vast, obviously exposes an immense area for criticism and attack The objection that, in taking all the civilisations he can find as his subjects of study, Prof Toynbee has included too much, may be summarily dismissed since it is the very range of his material and his endeavour to find common features in its diversity of detail that constitute the central intellectual interest of his inquiry Neither does it matter much, if at all, that he is not himself a first-hand authority over most of the field but has drawn freely on the labours of others An architect need not personally make or lay all the bricks in his house, and Prof Toynbee is an architect of ideas Nor, finally, is it very important that here and there he turns to conjecture to fill in gaps in our knowledge of perished civilisations, for what records have survived to our time is far more a matter of chance than what stages they must have traversed in the process of birth and growth Specialists may indeed question now and again Prof Toynbee's handling and interpretation of detail, but since he always gives both his evidence and his reasoning, his readers can agree, qualify or dissent for themselves Certainly men of science who use the

empirical method in other fields will not object to Prof Toynbee for using it in the study of human history

Since the "Study" is not yet complete, a final appraisal is not now possible Some of its central propositions are, however, sufficiently apparent Prof Toynbee regards civilisations as plural and not singular—an opinion which, though fundamental to the entire work, will certainly excite much criticism Given the facts, which he sets forth very fairly, many readers indeed will agree with him, and will reject the technique of those schools of historians who attempt to cram into the crannies of a single *a priori* mould the infinite complications of civilised history On the other hand, Prof Toynbee's argument equally implies that the life-histories of civilisations contain recurring and significant regularities, an inference which will also be challenged by the different school which regards history as altogether patternless Recurrence and significance, however, are largely questions of the scale, framework, and concepts of study, and if it be granted that civilisations are plural, if civilised societies as a species can be distinguished from primitive societies by their common features of size, longevity and rareness, and if some of the civilisations which have been born have also died, then negatively there can be no *a priori* reason why significant regularities should not recur, while positively Prof Toynbee's *a posteriori* conclusions as regards birth and growth, the only portions of his subject so far studied in detail, certainly ring too true to common experience to be dismissed out of hand

A book is more than the facts and arguments it contains, and no sympathetic reader can rise from Prof Toynbee's "Study" without paying tribute to the vitality, imagination, and generosity of spirit which suffuse its pages Treading a path which few forerunners have sought or found, he takes his readers up to a high place and shows them all the kingdoms of the earth stretched out in a great vista across space and time "The supreme task of the age," wrote *The Times* on its hundred-and-fiftieth birthday, "is a large enough inspiration" To the accomplishment of that task the "Study" should contribute

Short Notices

Air Ministry: Meteorological Office *British Rainfall, 1933 Seventy-third Annual Volume of the British Rainfall Organization Report on the Distribution of Rain in Space and Time over the British Isles during the Year 1933, as recorded by over 5000 Observers in Great Britain and Ireland.* (M O 375) Pp xvii + 293 + 4 plates. (London: H M Stationery Office, 1934) 15s net

THE general rainfall of 1933 was below the normal for the first time in eleven years, the percentage of the average of the 35 years 1881–1915 being only 80 for the British Isles as a whole, 82 for England, 80 for Scotland, 76 for Wales and 77 for Ireland Only an area in north-eastern England and a very small area in Hampshire had more rain than the normal in consequence of one or two heavy storms During the first quarter of the year, rainfall was more or less up to normal, there being a considerable excess in February, but October, and September in England, were the only other wet months June was remarkable for the exceptional number of violent thunderstorms, though the month was scarcely more impressive in this respect than June 1914 There were also heavy storms here and there in the later summer months, but the event of the year was undoubtedly the great snowstorm of February 23–26 in Ireland, Wales and part of England This is commemorated in the frontispiece showing a road heavily blocked with snow in Co. Carlow. An observer at Crickhowell in Breconshire, who was overtaken by the blizzard whilst on the mountains with some local farmers looking for sheep, states that they considered themselves lucky to have escaped with their lives, especially as they repeatedly had to take shelter in the rocks to avoid choking, so thick was the drift and so fierce the gale

As usual, this time-honoured annual contains some original papers These deal with percolation and evaporation at Grayshott in Hampshire by S E Ashmore, average rainfall over the county of London by J Glasspoole, and experiments with rain-gauge shields in exposed situations by F Hudleston Dr Glasspoole's paper shows the influence of relief on average rainfall even within the small area of London, but it seems to us a pity that he should have selected the now somewhat antiquated period 1881–1915 upon which to base the average rainfall of London It is now realised that meteorological averages are not stable In any event there is nothing sacrosanct about the 35-year period 1881–1915, even though it may be useful in our generation as a standard of comparison for other periods L C W. B.

Gmelins Handbuch der anorganischen Chemie. Achte Auflage Herausgegeben von der deutschen Chemischen Gesellschaft. System-Nummer 35: *Aluminium.* Teil A, Lieferung 1. Pp iv + 284. (Berlin: Verlag Chemie G.m.b.H., 1934.) 43 gold marks.

IT seems to be uncertain to whom should be ascribed the first successful isolation of the metal aluminium. Davy, Faraday and Berzelius all seem to have met with a certain amount of success, but in 1856 Berzelius stated that after many unsuccessful or only partially successful attempts by Davy, Oersted, Wöhler and himself to isolate the metal, it was

Wöhler who ultimately succeeded in 1827 Accordingly, Wöhler is generally given credit for the discovery, but in recent years Fogh has put forward a strong claim of priority on behalf of Oersted (1824–25), and has shown that Oersted's method of reducing anhydrous aluminium chloride with potassium amalgam and distilling off the mercury from the product can be made to give satisfactory results.

The origin of the important product kaolin is still somewhat obscure, although it is clear that kaolin results from the degradation of complex minerals, principally through the agency of carbon dioxide Disintegration of potash felspar may have been effected in three different ways, namely: (1) by the pneumolytic and hydrothermal action of volcanic gases, (2) by the action of atmospheric carbonic acid, and (3) by the action of vegetable acids from decayed organic matter. According to R Schwarz and R. Walcker, kaolin and laterite are not to be regarded as primary products of weathering, but rather as secondary compounds synthesised from the potash, alumina and silicic acid which are formed during the continuous hydrolytic dissociation of potash felspar. Such a theory would account for both the comparative scarcity of kaolin and also the simultaneous formation of other so-called products of weathering A table is given which shows the varying amounts of bauxite and laterite produced in various countries during the years 1925–31

The different metallurgical processes in use are described fully, particularly the Hall-Héroult process, in which remarkable success was achieved by the happy combination of a number of ideas, every one of which had already been in use for some time The remainder of the volume is devoted to the classification of the various physical properties of the metal

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Prof. Dr Emil Abderhalden Lief 420. Abt. 2: *Physikalische Methoden*, Teil 3, Heft 4 *Nachweis der biologisch wichtigen Körper durch Fluoreszenz und Fluoreszenzspektren* Von Charles Dhéré. Pp. 3097–3306. (Berlin und Wien. Urban und Schwarzenberg, 1933.) 11 50 gold marks

IN turning over the pages of this section of Abderhalden's great encyclopædia, one is impressed with the wealth of information imparted, much of which must be new to anyone not keeping abreast of current literature on the subject. The treatment is in four parts: (1) introduction (5 pages); (2) apparatus and methods (64 pages); (3) physical chemistry of fluorescence phenomena (20 pages); (4) a special part (96 pages).

The second part brings together in easily readable form detailed descriptions of a very wide range of apparatus and accessories, together with good practical accounts of their functions or applications In the next part, dealing with the physical chemistry of fluorescence, one finds a robust treatment of the fundamental principles and methods of experiment in general terms, but not in such detail as to serve as a laboratory manual Finally, in the special part, the work reaches its culminating point in the proving and identification of biological materials by fluorescence, and here the fruits of many thousands of applications are garnered Carbohydrates, glucosides, fats, phosphatides, proteins, porphyrins, chlorophyll, animal principles, alkaloids (especially the numerous cinchona bases), and several other classes of substances command individual consideration The book is well printed, the figures are good and the bibliography is rich in its detail

Die Chemie des Pyrrols Band 1 *Pyrrol und seine Derivate. Mehrkernige Pyrrolsysteme ohne Farbstoffcharakter* Von Hans Fischer und Hans Orth Pp xii+460 (Leipzig Akademische Verlagsgesellschaft m b H, 1934) 28 gold marks

THIS monograph on pyrrole chemistry satisfies a need which has long existed, for it is thirty years since an adequate account of the group has appeared No author could be better qualified for the present task than Hans Fischer, whose life-work has been to extend, and in many directions to create, the knowledge of the chemistry of both the simpler pyrroles and of the polynuclear pyrrole derivatives.

The volume under review contains the simpler pyrroles and the polynuclear pyrroles without pigment character, a second volume is to discuss the pyrrole pigments, the porphyrins and chlorophyll, etc, and the physiological side of pyrrole chemistry The work consists of a discussion of different types of pyrroles, their reactions and the methods for their synthesis, and provides at the same time a dictionary of all the pyrrole derivatives which are known Particularly valuable are the preparative methods which are given, and the authors' observations on the most suitable means of synthesis of a given pyrrole should be most useful to future workers As supplements are included an account of the derivatives of maleic acid obtained on oxidative degradation of pyrroles, which are therefore important for determination of constitution, also recommended methods for the preparation of starting materials for pyrrole synthesis Consultation is facilitated by an elaborate index. K F A.

Manual of Safety Requirements in Theatres and other Places of Public Entertainment. Issued by the Home Office, 1934 Pp ii+106 (London H.M. Stationery Office, 1935) 2*s*. 6*d* net.

THIS is a valuable, because most practical, summary of precautions against accidents of all kinds in places of public entertainment, with careful explanation of the reasons for them, and examples of disaster following neglect, and the 'requirements', mainly structural, and other 'conditions' to be observed by licensees Suggestions for improvement of any future edition are welcomed, and will no doubt be forthcoming to a book so considerately planned and clearly expressed. There is an excellent index, and diagrams are provided for the more important safety devices Everyone responsible for public entertainments should be acquainted with this manual

Canadian Water Power Developments during 1934

By Dr Brysson Cunningham

THE exploitation of hydro-electric power in Canada continues to make substantial progress, and as will be seen from the graph reproduced in Fig 1, from a report[1] recently issued by the Dominion Water Power and Hydrometric Bureau, the rate of development, despite the stagnation in trade, has not perceptibly slackened since the pronounced upward trend set in some fifteen years ago Although no new large water power undertakings were initiated during 1934, the continuation of work on a number of installations previously under construction led to the completion of new installations aggregating 214,965 horse-power, which were brought into operation during the year The total installation for the Dominion at the end of 1934 was 7,547,035 horse-power

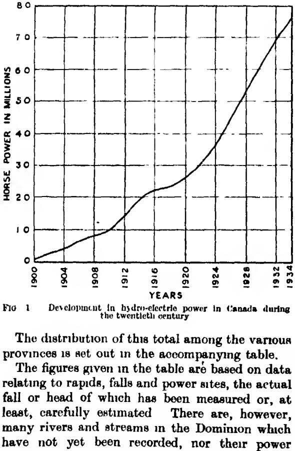

FIG 1 Development in hydro-electric power in Canada during the twentieth century

The distribution of this total among the various provinces is set out in the accompanying table.

The figures given in the table are based on data relating to rapids, falls and power sites, the actual fall or head of which has been measured or, at least, carefully estimated There are, however, many rivers and streams in the Dominion which have not yet been recorded, nor their power capacity determined These can only become available for tabulation as survey work proceeds, and much remains to be done in the less-explored districts of the north. Also, apart from definite studies of particular projects, no account has been taken of power concentrations which are feasible on rivers and streams of gradual gradient, where economic heads may be created by the formation of impounding dams As the actual water-wheel installation throughout the Dominion is found to average a development of power 30 per cent in excess of the tabular values for such cases, it is legitimate to infer that the present recorded water power resources of Canada will permit of a turbine installation aggregating about 43,700,000 horse-power, so that the realised power development at the present time is little more than 17 per cent of the ultimate possible development The figures in the table represent, in fact, the *minimum* water power possibilities of the Dominion.

In a previously issued statement[2], the Hon Thomas G Murphy, Minister of the Interior, commented on the situation and said that "the

AVAILABLE AND DEVELOPED WATER POWER IN CANADA, JANUARY 1, 1935

Province	Available 24 hour power at 80 per cent efficiency		Turbine installation
	At ordinary min flow	At ordinary six months flow	
1	2	3	4

Yukon and North West Terr	294,000	731,000	11 199
Total	20,347,400	33,619,200	7,547,035

recovery in power demand remarked in 1933 gained in momentum during 1934 and the records of electrical output compiled by the Dominion Bureau of Statistics indicate that the total output for 1934 will not only greatly exceed that for 1933 but will have established an all-time record" In point of fact, it actually attained an increase of nearly 19 per cent over the previous record of 1930

The increase in power installation during 1934 is principally accounted for by the completion of the Rapide Blanc development (about 160,000 horse-power) of the Shawinigan Water and Power Co on the St Maurice River, and by the installation of an additional unit (50,000 horse-power) for the Beauharnois Light, Heat and Power Co, near Montreal. The latter undertaking has already been described in NATURE[3], so that it is only necessary to refer to the former Through the courtesy of the Shawinigan Co., which has kindly

supplied particulars and photographs, it is possible to give a brief account of the important work at

Fig 2 Rapide Blanc power house and dam

Rapide Blanc The Company has previously exploited practically to the full extent, the hydraulic possibilities of the lower St Maurice River, which discharges into the St Lawrence at Trois Rivières, and their installations at Grand'mère, Shawinigan and La Gabelle, which were visited by the writer in 1927, have been described in Nature[4]

A view of the structural work of the dam and the exterior of the power house at Rapide Blanc is given in Fig 2, while Fig 3 is a view of the interior of the power house showing the arrangement of the turbines Unlike the installations of the Company elsewhere, there are no falls at Rapide Blanc, and the rapids themselves, before their submergence, were of no spectacular significance

The development is best described as a typical medium head water-power station, the main dam and power house being located on the St Maurice River at a point about 115 miles above Shawinigan Falls, which, in turn, are about 20 miles distant from Trois Rivières. The dam is of the usual standard gravity section, with the intake structure forming an integral part at the western end Flood regulation is secured by the use of four steel regulating gates, electrically operated, and suitably protected against extremes of weather Three of these gates are 50 feet wide by 36 feet deep, for the passage of 40,000 cu ft of water per second each, at normal water-level The fourth gate is also 50 feet wide, but only 16 feet deep. In addition, there are two smaller gates situated near the main gates for minor flow regulation

The water from the impounded area passes into the pump house through riveted steel penstock tubes, varying in diameter from 23 ft to 19 ft, the shell thickness being approximately ⅝ in The power house (Fig 3) will eventually contain six turbine generating units, of which four have been installed during 1934 The water wheels, supplied by the Dominion Engineering Works, Ltd, are rated at 38,000 horse-power each under 108 feet head and work at 109 1 rev per min Maximum efficiency is guaranteed as at least 90 per cent The electrical generators, contracted for by the Canadian Westinghouse Co, are of the vertical type, each rated at 30,000 k v a, generating current at 11,000 volts, 85 per cent power factor, three phase, 60 cycles

Fig 3 Interior of Rapide Blanc power house, showing arrangement of the turbines

and 109 1 r p m An unusual feature of the machines is that air is taken in for ventilating

purposes through the tops of the generators, as the main thrust bearings are located below the rotors. Power is transformed from 11,000 volts to 230,000 volts in outdoor water-cooled transformers, supplied by the Canadian General Electric Co., and is transmitted direct to Trois Rivières by means of an overhead transmission line, 120 miles long. With the addition of this installation, the Shawinigan Water and Power Co. possesses a combination of power plants aggregating 809,200 electrical horse-power and 55,000 hydraulic horse-power.

The enormous importance to Canada of its hydro-electric installations may be gauged from the fact that the investment represented by the present development of seven and a half million horse-power is conservatively estimated at 1,743,000 dollars and, while it is difficult to assign a precise figure to the coal equivalent of developed horse-power, the potential saving of coal through the present utilisation of water power is on a moderate computation equivalent to 36¼ million tons per annum. The realised saving, dependent, as it is, on the actual output of the plants in operation, was during the year 1934, of the order of 17 million tons of coal. The total installation gives a notable ratio of 697 horse-power per 1,000 of the population.

The Classification of Coals

By Dr. R. Lessing

THE complexity of the heterogeneous conglomerate, coal, can be appreciated if it is considered that it represents the accumulation of vast masses of a large variety of vegetable materials under different climatic and topographical conditions, and their gradual metamorphosis by biological, chemical and physical agencies extending over geological periods which have proceeded to, or are arrested at, varying stages of development. The component portions of a single plant differ widely in their morphological and phytological characteristics and more especially in their chemical composition, that is to say, in the general quantitative relationship of the cellulosic, lignitic, resinic groupings and their quota of normal inorganic plant constituents and accessories, and likewise in the qualitative properties of each of them. Assume this mixtum compositum of raw materials to be subjected to bacterial, enzymatic and chemical decay under varying conditions of wind and water, oxidation, dehydration and carbonisation, rest and disturbance, pressure of superimposed strata and disruptive earth movements, let these phenomena occur in different sequence, at different stages of 'coalification' and with different potency in each region, and you will sympathise with the researcher who attempts to piece the jig-saw puzzle of coal constitution together. He is faced with complexity in the smallest fragment examined under the microscope or by chemical analysis, in any lump taken from the domestic scuttle, when surveying a coal seam throughout its depth and along its bedding plane or a series of seams overlying each other in a single coal pit, when comparing the commercial products of any district or the deposits of the coalfields in different countries and continents.

Such considerations will demonstrate the difficulty of fitting the many hundreds of more or less definite forms in which coal occurs and their transitional modifications into a rigid system of classification. Moreover, classification is required for many purposes. The geologist, the palæobotanist, the chemist, the combustion or carbonisation engineer, the coal miner, and the coal salesman will all view the problem from their particular point of view, and will insist that any methodical grouping shall give the special information that satisfies their own curiosity or is helpful in their limited sphere of activity.

The older classifications of Karsten (1826), Regnault (1832), Gruner (1873), Hilt (1873), Schondorff (1875), and others were originally based on the character, and later the yield, of the coke obtained in the crucible test, and on the length of flame of the burning coal. This method has persisted on the Continent ever since, for commercial purposes, though admittedly deficient unless supplemented by other data. Attempts at correlating various properties led to the adoption of the ratio of 'fixed carbon' to volatile matter, the 'fuel-ratio', as a standard of comparison, particularly in America. In 1900, C. A. Seyler proposed a classification on the basis of the carbon/hydrogen ratio, and elaborated his scheme in recent years by incorporating the graphical representation of Ralston's isovols and isocals, and applying Parr's correction for mineral matter content. Seyler's classification is capable of expansion by plotting other characteristics, such as caking and agglutinating power, oxidisability, oxygen requirement

on combustion, hardness and liability to 'slacking' or weathering He visualises an atlas of the coals of the world in which the carbon and hydrogen axes correspond to longitude and latitude and the iso-functional lines to altitude, isotherms and other features of an atlas of physical geography

All attempts at coal classification prior to 1919 had dealt with commercial coals, that is, the mixed product of collieries in certain localities or at best the fuel extracted from individual seams The values used in drawing up coal charts were obtained by unstandardised methods of analysis, often of doubtful definition or accuracy, whilst the materials examined represented average samples, in most cases containing an undue percentage of adventitious mineral matter apart from the 'inherent' ash

In that year Dr Marie C Stopes described in the *Proceedings of the Royal Society* the four visible ingredients of banded bituminous coal—fusain, durain, clarain and vitrain—isolated mechanically from hand specimens from Hamstead Colliery in Staffordshire Reference had been made frequently in the literature to the banding of coal, to the dull (matt) and bright (glanz) nature of the laminations, and to the peculiar lenticular inclusions of mineral charcoal (mother-of-coal) This paper constituted the first attempt to consider coal in detail from a petrological point of view The possibility thus shown, of isolating distinct and identifiable components from any lump of banded coal, has proved a most fruitful factor in the furtherance of coal research during the past fifteen years, and its significance has penetrated even into the realm of industry The isolated components were shown to be different and typical in their chemical composition and morphological structure, to be associated with mineral matter in characteristic amount and composition, to have different coking values and to contain groups of organic compounds and plant residues in defined ratios

The subdivision of coal into the four visible Stopes ingredients has been widely accepted in Great Britain and in most European countries American workers have not felt able to adopt it in its entirety, owing partly to differences in the character of their coals and partly to difficulties in terminology They are adhering to the subdivision into Thiessen's anthraxylon and attritus, roughly comparable to clarain-vitrain and durain respectively. The fact that vitrain, clarain, durain and fusain are group designations and were put forward by Dr Stopes as merely representing portions of hand specimens distinguishable macroscopically has not been sufficiently appreciated by subsequent authors ; hence new observations on other coals have in some cases been interpreted as contradicting the original descriptions.

In a recent paper 'On the Petrology of banded Bituminous Coal'[1] Dr Stopes re-states her case and sums up the results of research arising from her original paper She goes further than that, encouraged by the additional knowledge obtained since its publication and in order to clarify the position, Dr Stopes proposes a much more comprehensive, though perhaps more ambitious, scheme of classification The new schedule[2], which during the last two years has been discussed in detail by the British and American members of the Coal Research Club and others, provides for the further subdivision of the macroscopic components into smaller groups, to which the generic term 'macerals' has been given, analogous to the minerals composing a rock These are connotated by the suffix *-inite* A maceral is named generally according to the kind of tissue from which it is mainly derived and of which in its mummified form the bulk of the unit consists If wood, cork, cortex, cuticles, spore exines or resin was the raw material, the maceral is called xylinite, suberinite, periblinite, cutinite, exinite or resinite respectively Completely jellified plant material is ulminite, whilst re-precipitated ulmin compounds form collinite Fusainised xylem or other lignified tissues are fusinite and the yet little explored matrix of durain or 'residuum' is termed micronite The combination of individual macerals present in the hand specimen (having suffix *-ain*) are vitrinite, fusinite, clarinite and durinite

In order to allow for the distinction between vitrains with and without structure, Potonié's terms pro-vitrain for the former and eu-vitrain for the latter are adopted, and in the case of vitrain the sub-groups ulmain, collain, periblain, suberain and xylain have been interposed between the main component and its macerals, to denote their principal characteristics

The schedule may at first glance appear complicated, and some may gibe at the mass-production of new terms These are, however, not meaningless words, but signify distinct elements which have been recognised and defined by the microscopist and the chemist Whilst the technique of identification and isolation of macerals has yet to be developed, the schedule forms a well thought out skeleton into which existing knowledge and future observations can be fitted The scheme is obviously of a tentative nature and mainly intended for the bituminous portion of the coal range, and not so much for coals of lower rank (peat, brown coal, lignite), but its potential bearing on coal research and practical coal classification should not be underrated

Classification hitherto had to be applied to complex mixtures It could be based with advantage even to-day on the characteristics of the

main components of coal If, however, in future by the combination of petrological and analytical data, the physical and chemical properties of the small units of the coal complex can be ascertained, the composite value of the fuel will be assessed with much greater accuracy than is possible at present What may, therefore, appear to-day as a somewhat academic problem, may to-morrow have a very definite effect on practical coal politics The coal producer, knowing that he can only sell the coal which he happens to find in his pit, usually stands aloof from attempts to codify coals in anything but a 'use' classification In Great Britain, even schemes for grading coal by size and freedom from ash and moisture have so far been regarded with disfavour The modern requirements of the industrial consumer, however, make more rigorous demands on the properties of coal used in his processes and indicate the necessity of defining these in terms different from the non-descript 'Derby Brights' beloved by the British householder in the past

Obituary

Prof Ganesh Prasad

We regret to announce that Prof Ganesh Prasad died on March 9, with unexpected suddenness Born in Ballia, a small town in the United Provinces, India, on November 15, 1876, Prasad took the D Sc degree of the University of Allahabad at the age of twenty-two years, and then studied at Cambridge and Göttingen as a Government of India scholar After serving for ten years as a professor of mathematics in his native province on his return from Europe, in 1914 he joined the University of Calcutta as the Ghosh professor of applied mathematics He left this post four years later to join the Benares Hindu University as its University professor, but came back to Calcutta in 1923, this time as the Hardinge professor of pure mathematics, which post he occupied until the time of his death While he was in the Benares Hindu University, he was also the principal of the Arts and Science College for about two years.

Prof Prasad was the first in India to create a school of mathematical research Many of the papers on mathematics published by young Indian investigators in the last twenty years bear an acknowledgment of indebtedness to him for guidance and help He founded the Benares Mathematical Society in 1918, and was its life-president. He had been for many years the president also of the Calcutta Mathematical Society

One of the earliest contributions made by Prof Prasad was his dissertation entitled "The Constitution of Matter and Analytical Theories of Heat" (1903), in which he dealt with the difficulty of interpreting differential coefficients when the molecular constitution of matter is taken into account. His papers on applied mathematics, published in various journals, dealt likewise with problems in which he skilfully applied his knowledge of the theory of functions of a real variable to potential problems in which the differential coefficients became infinite or did not exist. His later researches were on the theory of Fourier series and other branches of the theory of functions of a real variable. At the time of his death he had in hand the completion of a long memoir on "The Expansion of Zero", which he had promised to contribute to the first issue of the journal of the newly created National Institute of Sciences, India, of which he was a member of council

Prof Prasad was well known as a teacher, and his textbooks on the differential and integral calculus are still in use in many Indian universities His Patna University readership lectures on "The Place of Partial Differential Equations in Mathematical Physics" were published in 1924, and since 1928 he had devoted a good deal of his time to the writing of books on higher mathematics and on the history of the subject

Prof Prasad was much loved and admired by his numerous pupils, to whom he was always a source of great inspiration He was a man of wonderfully simple habits, and remarkable energy and powers of endurance He had a marvellous memory When he was a principal—to mention but one example—he recognised all the students (more than one thousand in number) and remembered not only their names but also numerous details about them

Gorakh Prasad

Dr. Shepherd Dawson

By the death of Dr Shepherd Dawson on March 26 at a relatively early age, experimental psychology in Great Britain has suffered a great loss For a period of many years, his experimental contributions have been published in the technical journals (mostly in the *British Journal of Psychology*) All have been marked by careful attention to the requirements of scientific method In later years his attention was directed towards the statistical problems of psychology, and a few years ago he published a book on statistics

Shepherd Dawson's earliest published work on various problems of vision already showed his quality as an accurate and painstaking experimentalist After he succeeded H J Watt as principal lecturer in psychology, logic and ethics at Jordanhill Training College, Glasgow, he did not lose his interest in experimental research. At meetings of the British Association he had generally some original investigation to report. Probably the best known of his later contributions to experimental psychology was his

work on "Persistence" carried out in collaboration with Prof E. P. Cathcart He had a real liking for apparatus, and few years passed during which he did not demonstrate at the meetings of the Scottish branch of the British Psychological Society (of which he was, at one time, president) some ingenious piece of apparatus which he had devised for practical work at Jordanhill He was closely associated with the work of Conn on the effects of encephalitis lethargica on intellectual development

When, last year, Shepherd Dawson became president of Section J (Psychology) of the British Association, he chose characteristically a subject both more scientific and more practical than that of most of his immediate predecessors, namely, "Psychology and Social Problems", in which he dealt with such urgent practical problems as the negative correlation between intelligence and fertility

Shepherd Dawson's interests lay almost entirely in the measurable aspects of psychology and not in introspective investigation or in theoretical psychology Within this field of the measurable, his interests were wide His own investigations were of a very varied nature, and he was widely interested in the work of others. He was generous in his gift of time and thought to all who asked his advice All who knew him will mourn his untimely end

R H T

SIR GEORGE SCOTT, K C I E

WE regret to record the death on April 4, at the age of eighty-three years, of Sir James George Scott Sir George Scott was well-known as an administrator in Burma, more especially for his success in dealing with the less-advanced tribes, concerning whom his writings are the best, and in some instances the only, authority.

James George Scott, the second son of the Rev George Scott of Dairsie, Fife, was born on December 25, 1851. He was educated in Germany and at University College School, London, the University of Edinburgh, and Lincoln College, Oxford He went to Perak as a war correspondent in 1875, and in 1879 joined the staff of St. John's College, Rangoon, where through contact with his pupils he laid the foundations of that knowledge of, and affection for, the peoples of Burma, which became the ruling force of his later life After witnessing French operations in Tonking as a correspondent of *The Times* in 1884, he served in a political capacity with the British expedition to Upper Burma and later joined the Government service as an Assistant Commissioner In 1887–88 he was employed in the Shan States and assisted in the pacification of the rebellious Shans

After serving on the Anglo-Siamese Boundary Commission in 1889–90, Scott was made superintendent of the Northern Shan States, and by his courage and personality made effective British influence over wild tribes who hitherto had been irreconcilable. From this time onward his career was a succession of difficult and responsible positions, each of which was in a sense a recognition of his previous success by promotion to a more difficult undertaking. Among those were service on the commissions which settled the Franco-Burmese and the Siamo-Burmese boundaries His knowledge of the Burmese peoples was put to good use when he was made responsible for the five volumes dealing with Upper Burma in the Census of 1901 He was made a K C I E in 1901, having been a Companion of the Order since 1892 In the following year Scott became Political Agent and Superintendent of the Southern Shan States and remained in that office until he retired in 1910 After his retirement his leisure was occupied in writing

Scott was a ready and versatile author His publications in book form began so long ago as 1882 with two volumes entitled "The Burman His Life and Notions" published under a Burmese pseudonym, while the first book to appear under his own name was "France and Tonking", published in 1885 Among his other works, apart from a number of novels, may be mentioned "Burma as it was, as it is, and as it will be" (1886), "Burma, a Handbook of Practical Information" (1906), a comprehensive account in which he was assisted by experts, "The Mythology of Indo China" (1918), "Burma from the earliest Times to the Present Day" (1924) and "Burma and Beyond" (1932), in which he recast and supplemented much of the information relating to tribes on the fringe of the British sphere of influence in his earlier works He was also a contributor to Hastings' "Encyclopædia of Religion and Ethics" and various scientific periodicals

PROF W J SINCLAIR

PROF WILLIAM JOHN SINCLAIR, who died at Princeton, New Jersey, on March 25, made many important contributions to our knowledge of fossil vertebrates, and added much to the palæontological museum of Princeton University, of which he had been director since 1927 He was born at San Francisco on May 13, 1877, and received his Ph D from the University of California in 1904 He removed to Princeton in 1905, became assistant professor in 1916, and was appointed professor of palæozoology in 1930

Prof Sinclair was specially interested in fossil mammals, and his most noteworthy work was his memoir on the fossil marsupials of Patagonia, published in 1906 in the reports on the Princeton University Expeditions to Patagonia, 1896–99 He concluded that the close resemblance between the Patagonian fossil Sparassodonts and the living Tasmanian Thylacine could only be explained by a former land connexion between South America and the Australian region

WE regret to announce the following deaths

Sir John Collie, chief medical officer of the Metropolitan Water Board, known for his work on the psychology of fraud, on April 4, aged seventy-four years.

Colonel W. G. King, C I E, distinguished for his work in connexion with public health in India, on April 4, aged eighty-three years

News and Views

The Formosa Earthquake

ON April 21, at 6 2 a m (local time), the most destructive of recorded earthquakes in Formosa devastated the two north-west provinces of Taichu and Shinchiku According to the latest official figures, 3,152 persons were killed and 8,991 injured, while 19,217 houses were destroyed and 18,472 damaged In the great earthquake of March 17, 1906, the corresponding numbers were 1,249, 2,378, 5,667 and 3,233 According to the Tokyo correspondent of *The Times* (April 22), the centre of the earthquake was in the upper reaches of the Koryuki river, the area of greatest damage being 50 miles long and 25 miles wide The focus is placed by the Japanese seismologists as near the surface at a point 25 miles north-east of Taichu At Taiho, fires broke out after the earthquake, and it is feared that the town will be completely destroyed Taichu suffered less, only about a hundred of 50,000 inhabitants being killed. Thus, the area chiefly affected runs from Taichu along a line parallel to the coast, but stopping short of Taihoku It is of some interest to note that this great shock occurred in a district in which earthquakes have been infrequent during the present century The principal zones are those in the districts of Kagi in central Formosa, and Karenko and Giran on the east coast To the Kagi centre belonged the earthquake of 1906 during which the crust was dislocated along a fault about 30 miles in length According to Omori (*Imp Earthq Inv Com Bull*, 1, 53–72, 1907), the displacement seems to have been unique In the western half, the ground on the north side was sheared relatively eastward and depressed, while, in the eastern half, the south side was sheared westward and depressed

Rural Water Supplies in Great Britain

THE subject of national water supplies again came up in the House of Commons on April 20 when on the motion for the adjournment Mr A Greenwood raised the question of the expenditure incurred by authorities in rural areas on the provision of new supplies, and inquired the Government's intentions in regard to the Water Supply (Exceptional Shortage Orders) Act which will lapse at the end of the present year unless steps are taken to extend it. Mr Alan Chorlton expressed regret that the water survey which at long last has been agreed to does not extend to allocation, and asked what steps are being taken within the Ministry of Health to set up a central body as advocated in the report of the water authorities. Mr G H Shakespeare, Parliamentary Secretary to the Ministry of Health, in reply, gave no indication whether a continuance of the emergency legislation will be necessary, but stated that the grant of one million pounds voted in aid of rural schemes last year has fostered the promotion of schemes estimated to cost three times that amount and is expected to do as much again during the current year. Out of just over 2,000 parishes requiring permanent sources of supply, schemes for 1,600 parishes have been prepared and are in various stages of realisation He alluded to the recently formed Water Survey Committee, and stated that two meetings have been held and that the Committee is actively pursuing its inquiries into the actual water supplies of the country

Award to Sir Aurel Stein

IT is announced that the gold medal of the Society of Antiquaries of London has been awarded to Sir Aurel Stein The services to archæology of Sir Aurel Stein, which are thus recognised by what may be regarded as the highest award in Great Britain for archæological studies, are too well known to need recapitulation His journeys in the Central Asiatic desert, and his excavations among its sand buried cities, pursued almost without intermission for more than thirty years at a cost of great personal hardship borne with never-failing endurance, have rewritten a long chapter in the history of Asiatic civilisation which had been lost, and brought to light the unsuspected glories of an art which had grown out of the otherwise unrecorded contacts of the classical world and India with the Far East His explorations of the lands of the North-West Frontier of India, among other discoveries, have retraced the march of Alexander the Great and illuminated the course of one of the great campaigns of world history While regret is universal that a nationalist policy in China should have put an end to Sir Aurel's investigation of the great complex of mountain and desert of Central Asia, by which he was unravelling the causes which led to the decay of this arena of a great civilisation, by diverting his activities to other fields, it may, should his hopes of discovery in Persia be realised, add still further to the indebtedness of archæological knowledge to his genius in exploration

Indian Art in Great Britain

IT is not surprising, in view of the long and intimate connexion of Great Britain and India, to learn that a search has revealed a number of examples of Indian art in public and private collections in Great Britain, which in the aggregate and in artistic quality and historic interest is impressive. In the last few months, Dr K N. Sita Ram, curator of the Central Museum, Lahore, according to a note in *The Times* of April 20, has been engaged in a comprehensive survey of the examples of Indian art and archæology in museums and art galleries throughout the British Isles. After identifying and cataloguing the Buddhist sculptures from Amravati in the British Museum, at the suggestion and with the co-operation of the Museums Association he has examined some fifty collections, travelling so far afield as Elgin, Dublin and Belfast Not only did he assist in rearranging and relabelling these collections, but he also advised on spurious or indifferent specimens, and in a number of instances discovered treasures which had been overlooked or of which the interest

had been unrecognised As a result of his inspection, choice specimens from private collections in several instances have now been placed in local museums Among the rarer and more unexpected of his finds are examples of Buddhist sculpture from Java at Edinburgh, Dublin, Elgin and Hawick, fine paintings of the Rajput, Kangra, and Moghul Schools at Halifax, Manchester and Edinburgh, and sculptures of the great Gandhara period and South Indian bronzes in many collections Dr Sita Ram, it is stated, is confident that without unduly depleting local collections, it is possible to get together ample material from Java and India now in the British Isles to provide for the central museum of Asiatic art and antiquities, which those who are interested in British national collections are convinced is an urgent need of the present time

Calendar Reform

THE International Fixed Calendar League, 1 Regent Street, London, S W 1, has issued a topical pamphlet entitled "How to Fix Easter and Establish Calendar Reform" The arguments for and against calendar reform bear some resemblance to the movement in favour of a 24 hour time system, which met with little encouragement from the public when it was given a trial by the B B C last year There is little solid, compelling argument in favour of either, though it would be a convenience in the long run to rationalise our methods of reckoning the hours of the clock and the days of the year It is claimed that the fixation of Easter would result in great public convenience, and that the equalisation of the number of days in each month, and in each quarter, would simplify statistics based on monthly and quarterly returns There are two rival schemes for calendar reform In the first there are twelve months, each quarter containing 31 + 30 + 30 days, and in the second thirteen months, each of 28 days. The stabilisation of the week and the month is to be obtained in either scheme by counting the 365th day in an ordinary year as Year Day, and by counting the 366th day in a Leap Year as Leap Day, neither day having a place in any week The International Fixed Calendar League casts a shadow on the respectability and balance of its arguments by exhibiting an intemperate preference for the 13 month plan as compared with the 12 month plan, it is claimed, for example, that the 13 month plan "would help research in science, health, etc" but that the 12-month plan would not ! It is extremely interesting to compare Pamphlet *E* for general consumption, with Leaflet *L*, "Fixed Calendar Benefits for Labour" (which was not sent to NATURE Office), in which the League indulges in an attempt to enlist the sympathies of the Labour movement in its scheme for calendar reform

Geographical Distribution of Unemployment

IN the issue of *Planning* dated March 26 (16 Queen Anne's Gate, London, S.W.1) some important facts relating to the geographical distribution of unemployment are emphasised with the aid of a diagram, wherein Great Britain is divided into two halves The first half, consisting of the Midlands, South and South West England, contains 6,319,000 insured persons between the ages of 16 and 64 years, while the second half, consisting of North England, Scotland and Wales, contains almost the same number, namely, 6,221,000 Yet the first half has less than 650,000 claimants to unemployment benefit and assistance, while the second half has nearly 1,300,000, or more than two thirds of the total registered unemployed If the comparison is confined to claimants for transitional payments and allowances—that is, to the able bodied unemployed coming under the Unemployment Assistance Board—the contrast is far more striking Less than a quarter of these cases occur in the first or more prosperous half and more than three quarters in the depressed half. Moreover, as there are large areas which are fairly prosperous even in the second half, the real concentration of the problem of able bodied unemployment for long spells is far narrower than regional figures show Another striking fact brought out is the relative insignificance of protracted unemployment among women workers

Printing by Wireless

ACCORDING to a report in *The Times* of April 20, a new instrument for wireless telegraphy, which will either handle the morse code or transmit and receive messages in plain letters, has recently been produced by Messrs Siemens and Halske of Germany, and is being demonstrated at the London offices of Messrs Siemens-Schuckert The instrument can be operated by any ordinary wireless set with an output of one or two watts, the frequency of the output signal being adjusted to be 900 cycles per second The mechanism consists of a short roller with a two-turn spiral or helix rotating over a paper tape and carbon paper, which are fed underneath On the arrival of a signal, paper and carbon are lifted sharply up against the helix by a blunt knife edge and, depending upon the duration of the blow, either a line or dot is printed The duration of the dot is about 1/500 of a second, while the system is capable of passing messages at a speed of about 50 words per minute No very elaborate means of synchronism between transmitter and receiver is required, and the apparatus is almost entirely free from atmospheric and other forms of electrical interference This new radio-telegraph printer is intended primarily for use in conditions where line-telegraphy is not possible, or where interference makes other methods of communication impossible At a demonstration in London, signals were received from the Königswusterhausen Station in Germany, using 8 kilowatts and sending out its ordinary service of news

Science in Everyday Life and the Schools

THE British Science Guild has recently organised a series of lectures on science which are intended to bring before the pupils of secondary schools some of the remarkable advances in scientific knowledge and in its applications to everyday life which are being

made at the present time The first two lectures were delivered in March to girls from London secondary schools by Mr C C. Paterson, director of the Research Laboratories of the General Electric Co., Ltd, Wembley, and have now been issued by the Guild as a pamphlet (Pp 20 1s) entitled "The Electron Liberated; its Industrial Consequences" They deal with the emission of electrons from hot and illuminated surfaces and the uses made of them in modern electrical engineering, in particular in the production of light. The mysterious dual character of the electron as a missile and a group of waves is not forgotten, and the necessity for more and better knowledge of its properties is insisted on The Guild is to be congratulated on the inaugural lecturer, to whom thousands of electrical engineers listened with such pleasure on the subject last year The sooner other schools can have the benefit of lectures of this type, the better it will be for our future citizens

Industrial Administration, at Loughborough College

FACILITIES for training in industrial administration and management are now increasing in Great Britain, the latest development being that at Loughborough College, where a Department of Industrial Administration was inaugurated last year The courses provided are of an intensive nature, extending over short periods, and the aim is to provide a kind of staff college for industry where executives may be given an insight into a larger range of administrative practice than they would be likely to obtain in the ordinary way The scope of the new department is thus somewhat different from those now well established at the Manchester College of Technology, or the London School of Economics, which provide courses extending over one or two academic years The facilities provided at Loughborough include week-end, ten day and longer courses adapted to the degree of experience of those attending Instruction includes lectures, organised reading, group discussions, personal discussion of individual problems and visits to works and offices It is intended that the week-end courses should be confined to executives with practical experience in the same industry, and in the first instance, these are being provided for engineering executives and will deal with such special topics as costing, rate-fixing and progress control In the prospectus of the Department, it is pointed out that the various courses are of especial value to owner-managers who have not been able to acquire experience in other businesses, and to executives whose experience has been confined to a restricted field.

Meteorology of the South Seas

APIA OBSERVATORY, in Western Samoa, is under the control of the Department of Scientific and Industrial Research, New Zealand, and the work is directed by Mr. J. Wadsworth, formerly in the Meteorological Office, Air Ministry, who has recently presented his report for 1932 to the Observatory Board in the form of a compact and very clearly printed little volume of 114 pages. The report is a summary of observations in terrestrial magnetism, seismology, meteorology and atmospheric electricity. Synoptic weather charts were made on every day of the year, the data being collected by the wireless station at Apia from twenty observing stations in other groups of islands in the South Pacific, and sometimes from passing ships Since May 1932 a daily weather report has been exhibited at the Post Office and Customs House in Apia, at the request of local shipowners Considering the small size of the staff, which consists of the director and two scientific assistants and four locally recruited clerks, the amount of work accomplished, especially on the purely meteorological side, seems highly satisfactory Upper winds were measured with the aid of pilot balloons on seventy-eight occasions, the usual meteorological instruments were maintained, while in addition a Piché evaporimeter and a Wilson radio integrator were read daily at 9 a m The meteorological summaries are so detailed that a very clear idea can be formed of the weather experienced from day to day in this part of the South Seas, they include, also, less detailed climatological summaries from other groups of islands An even fuller programme was contemplated, for arrangements were being made for re-conditioning and bringing into use a spectroheliosope which was obtained on loan from Mount Wilson Observatory

Standardisation of Insecticides and Fungicides

THE standardisation of insecticides and fungicides has for some years been a matter of discussion among both the users and manufacturers of these chemicals, and requests from farmers and growers that the content of active materials in these products should be guaranteed resulted in the publication by the Ministry of Agriculture of specifications of a number of those most generally in use (Advisory Leaflet No 9) To meet the recent great development in the employment of insecticides and fungicides, a further publication has now been issued by the Ministry, namely, Bulletin 82, "Specifications and Methods of Analysis for Certain Insecticides and Fungicides" (London · H M Stationery Office 3*d*. net) In this bulletin, the specifications already published have been brought up to date, and additional specifications for certain compounds such as copper fungicides, not previously dealt with, have been included In addition, agreed methods of analysis, drawn up in connexion with the specifications, are supplied. Both specifications and analytical methods have been accepted by the Association of British Insecticide Manufacturers, the Government Laboratory, the National Farmer's Union and the Ministry of Agriculture. Purchasers are strongly advised to require a guarantee that materials supplied comply with these specifications, for, by so doing, they ensure that they obtain standard products of high quality.

Lancashire Sea-Fisheries Research

THE report for 1932 (No. 41) on the Lancashire Sea-Fisheries Laboratory at the University of Liverpool (1933), edited by Dr. R. J. Daniel, is in

future to be incorporated with the *Proceedings and Transactions of the Liverpool Biological Society* and not issued separately. The present report includes accounts of experimental lobster rearing by W C Smith, plaice marking in the Irish Sea by R J Daniel and R A Fleming, and a comparative study of the abdominal musculature in Malacostraca (Part III) by R J Daniel This last paper is a continuation of Dr. Daniel's work on the muscles of various Crustacea which have been published in the Lancashire Sea-Fisheries Reports in 1927, 1929 and 1932, and describes the musculature of *Lophogaster typicus* and *Gnathophausia zoea* The weight of evidence shows a close affinity between the Euphausiacea and the lower decapods, although there are apparent similarities between *Meganyctiphanes* on one hand and *Lophogaster*, *Gnathophausia* and *Praunus* on the other. It is concluded by the author, after very careful consideration, that the former represents a true relationship (homology) and that similarities between mysids and euphausids are due to convergence These researches on the abdominal muscles are carefully and beautifully worked out and are accompanied by fine drawings

Welfare Problems in India

IMPENDING constitutional changes, which will affect welfare administration in India, add particular significance to two articles by Mr Cedric Dover in the January issues of *Mother and Child* and the *Quarterly Review*. He discusses the organisation and condition of maternal and child welfare in India, and the needs and defects of welfare legislation Maternal mortality rates are 4–20 times, and infant mortality rates 3–4 times as much as the averages obtaining in England, and are closely correlated with communal prosperity and housing conditions An interesting biological correlation is that between climatic conditions and frequency of conceptions, the maximum number occurring in Bombay during the period of minimum humidity (January–April) Both articles emphasise the need for centralisation and greater co-ordination of welfare activities A consolidated Public Health Act for all India is regarded as the primary essential of welfare legislation, and a commission on legal reform is suggested, which will recognise that "the main object of law is the prevention of dysgenic, and the encouragement and establishment of eugenic forces", unimpeded by traditional beliefs The operation of Hindu, Mohammedan and Christian laws under one administration is dismissed as "an anachronism that needs no emphasis".

Commercial Timbers of the Punjab

A Forest Bulletin, No. 84, in the Economy Series of the Imperial Forest Research Institute, Dehra Dun, has been recently issued (Delhi: Manager of Publications, 1934) entitled the "Identification of the Commercial Timbers of the Punjab" by K. A. Chowdhury, wood technologist. The Indian Research Institute has been a pioneer in getting together information on the timbers of a definite region, having undertaken intensive research in the timber resources of India during the past twenty years; with the result that the number of timbers now sold in the market is much greater than it was a few years ago This fact, states the author, has resulted in difficulties in identification of some of the species which have now come upon the market The aim of the Bulletin, and a predecessor on Burma timbers, is primarily to show the differences of the anatomical structure of some of the more commercial timbers of the Punjab, and the way to identify them on the spot with the assistance only of a hand lens and pocket knife Brief notes are also given on the strengths, seasoning properties, durability, working qualities and uses for each species these latter add greatly to the practical value of the publication The commercial woods of the Punjab, of which a proportion are temperate species, both conifer and broad-leaved species, are comparatively few in number and their identification is by no means difficult Those who make use of this Bulletin will find the excellent low power ($\times$ 10) photomicrographs of considerable assistance The species dealt with include the Himalayan conifers, deodar, spruce and silver firs, several pines and broad-leaved trees such as walnut, several oaks, box-wood, poplar and alder, and the Plains species, such as sál, mango, tun, sissoo, tamarix and so forth

Chemical Research in Czechoslovakia

UNINFLUENCED by the economic depression, which has been felt in Central Europe as keenly as elsewhere, the various schools of chemical research in Czechoslovakia have continued their activities with undiminished energy, as is apparent from the papers published in vol 6 of the *Collection of Czechoslovak Chemical Communications* In inorganic chemistry, Dr. Škramovský's 'stathmographic apparatus' has found further application in the study of complex inorganic salts such as the bismuth oxalates. The apparatus automatically records photographically the change in weight of a substance with, for example, increasing temperature Striking dehydration curves have been obtained and results are found to vary according to well-defined circumstances Thus copper sulphate crystals from aqueous solutions show quite different behaviour from those from alcoholic solutions. Further, inoculation with lower hydrated salt causes characteristic changes in the curves photographically recorded The stathmographic method thus seems to promise a new field of investigation in inorganic chemistry. In physical chemistry, the Prague polarographic school has published further work especially in connexion with the catalytic evolution of hydrogen at the dropping mercury cathode, which can be made use of in micro-analytical tests Revenda's work in Prof Heyrovský's laboratory has extended the applicability of polarographic analysis to the anions In organic chemistry, the *Collection* includes results of researches by Prof Votoček and his collaborators on new conversions of sugars to furane compounds New glucosyl-alkyl-amines are described, and the constitution of fuco-hexonic and rhodeo-hexonic acids has been worked out.

American Geophysical Union

THE American Geophysical Union, established in 1919 as the American National Committee of the International Union for Geodesy and Geophysics, held its annual congress this year at Washington, on April 26–28, and one of its sections met again at Berkeley, California, on June 20–21 All the seven sections of the Union, for geodesy, seismology, meteorology, terrestrial magnetism and electricity, oceanography, volcanology, and hydrology, met at Washington Only the hydrology section was represented at Berkeley, where its meetings were associated with the Western Inter-State Snow Survey Conference The report of the Union is this year published in two volumes (reproduced direct from typescript, as in recent years), of which the first, of 257 pages, relates to the General Assembly and the first six sections; the second volume is still larger, of 370 pages, and forms a striking illustration of the attention now being devoted in the United States to the many aspects of hydrology—a subject almost neglected in Great Britain. The volumes contain very many short scientific papers of great interest, as well as formal reports on work in progress

Mining Research at Birmingham

WE have received the report of the work of the Mining Research Laboratory in the University of Birmingham during the year 1933, which has again been financed by the British Colliery Owners' Research Association and by the Miners' Welfare Fund This executive board of mining research is doing excellent work under the chairmanship of Dr J. S Haldane Again this year silicosis is investigated, but in accordance with Dr. Haldane's repeatedly expressed opinions, the work appears to be confined to the determination of 'free' silica; Dr W Jones's investigations are not referred to Nystagmus, which was carefully investigated previously, is not specially discussed, although the investigation of underground illumination no doubt will play a very important part in minimising the incidence of this distressing and costly complaint. Much appears to have been done with regard to the production of gas of high calorific power from coal or coke oven gas, and various investigations tending to improve atmospheric conditions underground as well as investigations into the physiology of the miner will no doubt prove of great value in the future

Calculations for Draughtsmen

THE Association of Engineering and Shipbuilding Draughtsmen has recently added to its useful series of pamphlets one on "Some Notes on Deflection", by Mr. W. R. Thomson, and another on "Mechanical Design of High-Speed Salient-Pole A.C. Rotors", by W. R Needham. In the first of these the author gives a logical account of the principles of deflection of cantilevers and simply supported beams. No advanced mathematics is used, rough sketches being sufficient to give the figures necessary for the deflection calculations, which are made by slide rule. In the second pamphlet, Mr. Needham deals with shafts and bearings, shaft stresses, critical speeds, rotor bodies, rotor poles, coil supports and balancing. The stresses in high-speed rotors are of a very high order, and the centrifugal force of a single pole and coil, says the author, at the overspeed may exceed a million and a half pounds. The overspeed in some hydro-electric machines may exceed the normal by as much as 100 per cent

Bibliography of Seismology

A NEW volume (No 12) of the Publications of the Dominion Observatory (Ottawa) is, we are informed, to be devoted to the bibliography of seismology. The first part, issued recently, contains notices of memoirs for the first quarter of the present year It may be noted that vol 10 of the Publications includes the titles of 2,000 memoirs for the years 1929–33 A still earlier series, in which notices of 1,200 memoirs appeared, was issued under the auspices of the Eastern Section of the Seismological Society of America and was published in vol 17–19 of the *Bulletin* of the Society Both series were prepared by the present editor, Mr E A Hodgson, who has now the assistance of twenty-four collaborators All the important countries in which earthquakes are studied are represented on this list, with the exception, we regret to notice, of Great Britain

Diseases of Swedes

A NEW bulletin (No 74) issued by the Ministry of Agriculture (H M. Stationery Office, 1*s*) is concerned with two diseases of swedes. Experiments with pure culture have shown that canker, which affects the seed-bearing plant, and dry rot which attacks the roots, are both due to the same fungus, *Phoma Lingam*. This fact is of importance, as infected seed would be likely to result in an infected root crop The disease is not serious in England, but has become prevalent in New Zealand; and since most of the seed used there is obtained from Great Britain the question of infection is important. Methods of seed sterilisation have been sought with no great success, but evidence has been obtained that weeds afford a serious source of infection. Good cultivation would, therefore, seem as necessary as clean seed if spread of the infection is to be avoided.

Population Problems

THE third General Assembly of the International Union for the Scientific Investigation of Population Problems will be held in Berlin on September 9, at 11 a.m., in the rooms of the University. An International Congress will be held in Berlin on September 10–15 under the auspices of the International Union. The Congress will have the following divisions: (1) Population Statistics; (2) Biology and Race Hygiene; (3) Social, Economic and Psychological Problems of Population; (4) Medicine and Hygiene. The business office of the Congress is, Berlin W 62, Einemstrasse 11.

Congress of Anthropology

THE sixteenth Congress of Anthropology and Prehistoric Archæology will be held at Brussels from

September 1–8. It will consist of the following sections : morphological and functional anthropology, blood groups, human palæontology, heredity and selection, psycho sociology, criminal anthropology, ethnography, folk-lore and history of religions. Further information can be obtained from the general secretary, Dr Dekeyser, 9 rue des Sablons, Brussels

The Sky in May

VENUS continues to be a brilliant evening object Both its brilliance and its eastern elongation are still increasing Mars passed through opposition on April 6, and is now an evening object It will be stationary on May 19. The planet is very conspicuous in the southern sky just before midnight Mars has been very close to γ Virginis during the last week in April This star is worth examining with a small telescope as it is a double star which is easily resolved, the two components, whose magnitudes are 3^m65 and 3^m68, being six seconds of arc apart. Jupiter is in opposition on May 10. The planet is rather far south of the equator Saturn is still a morning object. The moon will occult the bright star δ Geminorum on May 7 Both disappearance and reappearance will be visible at Greenwich, taking place at 21^h59^m and 22^h56^m G M T. respectively

Announcements

PROF. A. C SEWARD, professor of botany in the University of Cambridge, has been elected a member of the Norwegian Academy of Science and Letters, and also an honorary fellow of the Indian Academy of Sciences, Bangalore

As a token of their admiration, the friends of Sir Arthur Evans in the Mediterranean have subscribed towards the cost of a portrait-bust of himself to be presented to him in recognition of his pioneer work in the exploration of the Mediterranean bronze age civilisation at Knossos. The presentation took place on April 14 in the Museum at Candia in the presence of a numerous body of friends and admirers.

THE thirteenth award of the Faraday Medal of the Institution of Electrical Engineers will be presented to Dr. F. B. Jewett, of New York, at the ordinary meeting of the Institution to be held on May 2. The presentation will precede the twenty-sixth Kelvin Lecture, which will be delivered by Sir William Bragg, on "The Molecular Structure of Dielectrics".

THE forty-first James Forrest Lecture of the Institution of Civil Engineers will be delivered on May 14 by Prof. O. T. Jones, Woodwardian professor of geology in the University of Cambridge, who will speak on "Geophysics".

THE Royal Geographical Society has made the following awards for 1935 : Murchison Grant, to Mr. R. P. Bishop, for his surveys in British Columbia and other services to geography ; Back Grant to Mr Wilfred Thesiger, for his journey through the Danakil country, 1933–34 , Cuthbert Peek Grant to Mr A R Glen, for his work in Spitsbergen, particularly his leadership of the Oxford University Expedition, 1933 , Gill Memorial to Mr E E. Shipton, for his plane-table surveys of the inner Nanda Devi basin and the neighbouring watersheds.

PROF W L BRAGG will deliver the twenty-fifth annual May Lecture to the Institute of Metals on May 8 in the hall of the Institution of Mechanical Engineers, Storey's Gate, Westminster, S W 1, at 8 p m The subject of Prof Bragg's lecture will be "Atomic Arrangements in Metals and Alloys" Tickets of admission can be obtained from the Secretary of the Institute of Metals, 36 Victoria Street, London, S W 1

DRS. ACHARD, Lapicque and Mayer of Paris, Policard of Lyons and Bouin and Vlès of Strasbourg have been elected members of the section of biological sciences in the French Superior Council of scientific research, and Drs Martin, director of Institut Pasteur, and Roussy, of the faculty of medicine of Paris, extraordinary members

THE August Forel foundation of the German Academy of Natural Sciences at Halle, which is to award a prize every two years for researches in the subjects in which Forel was specially interested (eugenics, the alcohol problem, study of ants and the central nervous system), has recently made its first award to Dr Graf, who is head of the department of industrial physiology at the Kaiser Wilhelm Institute of Dortmund

AN index to the *Astrophysical Journal* covering the issues of January 1920–June 1932 (vols 51–75) will be published in May It can be obtained, price 2 60 dollars, including postage, from the University of Chicago Press, 5750 Ellis Avenue, Chicago, Illinois.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—A lecturer in zoology in the University of Capetown—The Secretary to the High Commissioner of the Union of South Africa, Trafalgar Square, London, W.C.2 (April 30). A lecturer in the Engineering Department, College of Technology, Leicester—The Registrar (May 4) A junior scientific officer in the Scientific Research Pool, Air Ministry—Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (May 4). A temporary engineering assistant in the Directorate of Works, War Office—The Under-Secretary of State (C 5), The War Office, S.W.1 (May 6). Inspectors in connexion with Agricultural and Horticultural Education and Research under the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1 (May 13). A physicist in the Radium and X-Ray Therapeutic Departments of the General Infirmary, Leeds—The Secretary (May 18). A lecturer in mathematics at the Royal Technical College, Glasgow—The Secretary.

Letters to the Editor

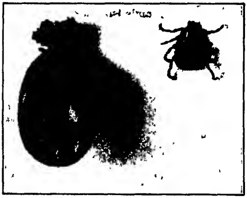
The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 659.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Winter Feeding of the Tick, *Dermacentor andersoni*, Styles

ONE of us (J D G) recently engaged in investigating the feeding habits of ticks at the Dominion Entomological Station at Kamloops, British Columbia, with special reference to the dissemination of disease—at the end of September, 1934, brought to the zoological laboratory at the University of Alberta, Edmonton, a limited number of adults of *Dermacentor andersoni* (native at Kamloops) for winter study In contrast to their behaviour through the summer months, these ticks consistently refused to feed when brought to Edmonton in the autumn Incidentally, one



B A

FIG 1 *A* Adult female tick (*D andersoni*) unfed *B* Engorged female, at the commencement of egg-laying, February 10, 1935 × 3

individual placed on a sheep at Kamloops, as early as the beginning of September, had refused to engorge and was finally removed after two weeks This observation appears to agree with the experience of the Rocky Mountain Laboratory at Hamilton, Montana, where thousands of ticks are reared annually

In all, eight adults were used on domestic rabbits and man (J D G.) during November and December, but although willing to attach or to shift their positions and re-attach, none of them attempted to engorge (or if they attempted it, did not succeed) during the six days that constituted the test period in each case.

The ticks being useless for practical purposes whilst behaving like this, it was suggested by the other of us (W. R) that if appropriate modification could be induced in the physiological state of the host, the parasite might exhibit a corresponding change of behaviour upon attachment The scheme of controlled illumination originally used on the *Junco*[1], resulting in the conversion of a sexually dormant autumn individual into a fully sexed spring bird in a few weeks and evidently conducive to profound changes in physiology and metabolism, suggested an obvious method of treatment which was accordingly adopted.

On December 14 a domestic rabbit was provided with a cage in which illumination could be precisely controlled, and for the week following was restricted to a day of seven hours duration On the eighth and subsequent days the period of illumination (ordinary electric light bulbs) was increased by ten minutes daily A month later an adult, unfed tick (which had received no illumination or analogous treatment) was placed on the rabbit It attached almost immediately and was replete at the end of two weeks (The normal summer engorging period for *D andersoni* is nine days) Two more adults were then simultaneously applied but both, unfortunately, were females One of these had failed to feed on man at the end of November but now, after two days of indecisive attachments, began to engorge and was replete on the fifteenth day Eight days after removal it began to lay eggs, inevitably infertile (Fig 1) The second individual changed positions spasmodically for a week, when engorgement ensued

Depletion of the stock of adult ticks permitted the use of only one other This was first placed on an untreated rabbit, on which it remained attached for five days without signs of engorgement. It was then transferred to the illuminated host, caged under an opaque capsule strapped to the skin of the rabbit, with intervening water baths absorbing the heat from the illuminating bulbs It attached itself permanently on the fourth day, when engorgement commenced

An additional supply of newly emerged adult ticks was received from Kamloops on February 18. In view of the fact that by this date the days had been lengthening for two months, three were at once placed on an ordinary stock rabbit. Two attached and began engorging on February 19 The third has failed to engorge to date.

The limited material that has been available would, no doubt, make a lengthy discussion of these results premature The most suggestive points are self-evident They seem to be sufficiently novel, however, to justify publication at this stage and to warrant repetition and expansion in the future.

The Antihæmorrhagic Vitamin of the Chick

OCCURRENCE AND CHEMICAL NATURE

IN earlier papers[1,2] a new deficiency disease in chicks has been described which is characterised by a tendency to large hæmorrhages. It has been ascribed to the lack of a specific antihæmorrhagic factor which is different from vitamin C. More recent work has demonstrated that the factor in question is a fat-soluble vitamin occurring in hog

liver fat, in hemp seed and certain vegetables, such as tomatoes and kale, and—to a less degree—in many cereals Beef muscle, calf brain and beef lungs desiccated at low temperature are ineffective when they form 20 per cent of the diet, but 20 per cent of dried hog liver will prevent the disease

The antihæmorrhagic vitamin cannot be identical with A and D, since very large doses of these vitamins in the form of concentrates or fish liver oils are ineffective Commercial (α, β) carotene or 4–10 per cent of fresh wheat germ oil do not prevent the disease, but large amounts of wheat-germ oil (24 per cent) afford some protection 3-4 per cent of hog liver fat will completely suppress the symptoms

The vitamin occurs in the easily soluble non-sterol fraction of the non saponifiable matter In hog liver fat it is not destroyed to any great extent by 12 hours heating as a layer 1–2 mm. deep on a boiling water bath, but it appears that there is some loss during the concentration process When the petrol-ether solution of the non saponifiable concentrate is shaken with 90 per cent methyl alcohol, the vitamin remains in the petrol-ether It resembles in these respects vitamin E Further concentration by means of chromatographic adsorption and vacuum distillation using a standardisation method of Schönheyder described below is under investigation

Since hog liver fat is many times as active as wheat-germ oil, it is very unlikely that the anti hæmorrhagic vitamin is identical with vitamin E. I therefore suggest the term *vitamin K* for the antihæmorrhagic factor

It has not been possible to demonstrate the requirement of the antihæmorrhagic vitamin for other animals than chicks, but this point is being investigated further.

MEASUREMENT AND BIOLOGICAL ACTION

IN a recent paper[1] a deficiency disease in chicks was described, the main symptoms of which were a tendency to large hæmorrhages, certain pathological changes in the gizzard and anæmia The blood of chicks suffering from this disease has a considerably prolonged clotting time, which is undoubtedly connected with these symptoms. McFarlane *et al* [2] have made the same observation on chicks reared on an insufficient diet.

The clotting time has been determined in the following ways. (1) The brachial vein was opened by a slight cut and 2–3 ml blood allowed to drop slowly, during ½–¾ minute, into a small porcelain bowl The time from the vein puncture until complete clotting is called clotting time, which for normal chicks is 1–5 minutes, while it may be several hours for the sick animals. In spite of the roughness of the method, it differentiates between sound and sick animals, and the results are in accordance with those obtained by the following more exact method of measuring the clotting time. (2) The carotid artery is dissected free, a cannula is inserted into the lumen of the vessel and by means of a record syringe 2–3 ml. blood is aspirated and then placed in paraffin coated tubes previously cooled to 0° C The tubes are centrifuged and the supernatant plasma is removed with pipettes into tubes, corked and stored in an ice box This plasma will clot only after addition of a clotting agent (embryonic tissue or lung tissue juice)

Normal and sick plasma show an enormous difference in the clotting time under the same conditions and towards the same clotting agent (technique Albert Fischer[3]) By increasing the concentration of the clotting agent a sick plasma can be made to clot as quickly as the normal The concentration of the clotting agent which clots the normal plasma in 3 min is called 10 That multiple of the concentration 10 which is necessary to clot a sick plasma in 3 min will be a quantitative expression of the morbidity of the animal The plasma of a sick animal will become perfectly normal in a few days by adding a sufficient amount of vitamin K

The quantitative determination of vitamin K is based upon the curative method One unit of vitamin K is the smallest amount which during a certain time can bring a sick animal with a certain degree of morbidity to the normal state with respect to the clotting time

It is difficult to explain theoretically the prolonged clotting time of the blood from a sick animal since there are no morphological changes in the blood, or changes in the fibrinogen or calcium content A change of *p*H is also not the cause The content of the thrombokinase in the tissue of the sick animals is not reduced, nor is there any increase in the content of antiprothrombin in the plasma *The investigations have shown, however, that in normal plasma a component is present which accelerates the clotting of the plasma from sick animals*, even if the concentration of the normal plasma is very small (a few per cent)

It is supposed that lack of vitamin K causes a decrease of the clotting accelerating component in the blood The nature of this component as well as its possible rôle in animal and human pathology is now under investigation

Loss of Velocity of Neutrons in Heavy Water

WE have made some experiments on the Fermi effect produced in silver, when the neutrons are allowed to pass through a layer of heavy water We used double-walled cylindrical glass vessels which could be filled with ordinary water or heavy water of 98 per cent purity The neutron source, a tube containing radon mixed with beryllium powder, was placed in the narrow inner tube of this double walled vessel

The vessels were of two different sizes the smaller ones contained 8 8 gm D_2O or 8 gm H_2O, the difference of radii of the inner and outer cylindrical surfaces of the liquid being 9 5 mm, the larger vessels contained 26 gm. D_2O or 23 4 gm. H_2O, the difference of radii being 15 5 mm During exposure, a silver receiver was pressed against the outer walls of the vessel surrounding the source, and the activity measured afterwards under standard conditions with

a Geiger counter. With each type of vessel we counted the impulses due to induced activity (*a*) when the vessel was empty, (*b*) when it contained heavy water, (*c*) when it contained ordinary water. The results are shown in the accompanying table; the figures are the total number of counts obtained in thirty experiments for each entry. The ratio of the figures in Column *a* is equal very approximately to the ratio of solid angles subtended in both cases.

Absorbing layer	Empty vessel (*a*)	Vessel with heavy water (*b*)	Vessel with ordinary water (*c*)	*b/a*	*c/a*
9.5 mm	1556	1898	4043	1.22	2.6
15.5 mm	654	1335	4173	2.04	6.4

We see that the efficiency of neutrons in producing the Fermi effect is considerably increased when the neutrons pass through a comparatively thin layer of heavy water. This increase must be ascribed to the slowing down of neutrons resulting from their collisions with diplons. The effect is smaller in heavy than in ordinary water because in a head-on collision with a diplon the neutron loses only two thirds of its velocity. Calling d_1 and h_1 the coefficients by which the efficiency of neutrons is multiplied when they pass through 9.5 mm. heavy and ordinary water, d_2 and h_2 the corresponding coefficients for the thickness 15.5 mm., we see that d_2/d_1^2 is greater than h_2/h_1^2. This means that a small increase of the thickness of the scatterer corresponds to a *relatively* greater increase of the coefficient *d* (heavy water) than of the coefficient *h* (ordinary water). This difference is probably due to the fact that in the case of collisions with diplons the effective scattering takes place mostly in the backward direction, while in the case of collisions with protons the scattering is always in the forward direction. For this reason, in our arrangement multiple scattering must play a more prominent rôle in heavy than in ordinary water.

Experiments on the slowing down of neutrons in compounds of hydrogen were made by Westcott and Bjerge[1], who were led to the conclusion that the mean free path of the neutron in the scatterer decreases with their velocity and that their efficiency in silver is inversely proportional to the energy. Assuming that the cross sections of diplons and protons for collisions with neutrons are only slightly different, we find that the ideas put forward by Westcott and Bjerge account also in a satisfactory way for our experiments.

We have satisfied ourselves that the effect of heavy water described in this letter is not due to neutrons produced in heavy water by the gamma rays of radium C′[2], because with the small quantity of radon (40 millicuries) at our disposal, no radioactivity could be detected in silver exposed to a tube containing radon but no beryllium and surrounded by 26 gm. heavy water.

Atmospheric Condensation Nuclei

WE have measured the diffusion coefficients and the rates of fall under gravity in air of atmospheric condensation nuclei. The values obtained for the diffusion coefficients are fairly consistent, the average being about $D = 18 \times 10^{-6}$ cm.²/sec. The well-known relation between mobility in an electric field and diffusion coefficient gives mobility $= D \times eN/P$. If e is the electronic charge, eN/P is very nearly 40, and the corresponding mobility is $7 \cdot 2 \times 10^{-4}$ cm./sec./volt/cm., which is a probable average value for the mobility of the large atmospheric ion.

The values obtained for the rate of fall show more scatter, but observations made with two apparatus of quite different construction agree in giving a mean value of about 0.7×10^{-4} cm./sec. Comparing the rate of fall under gravity with the mobility, we have $mg \times 300/e = 0.7/7.2$. This gives for the mass of the condensation nucleus $m = 1.6 \times 10^{-16}$ gram. If it be assumed that the nucleus is composed for the greater part of water, the radius corresponding to this mass is $3 \cdot 4 \times 10^{-6}$ cm. This is in good agreement with values derived by the application of the Stokes-Cunningham law to mobility data.

Details of the experimental methods employed will be given in a later publication. From results already obtained, it appears that by these methods it will be readily possible to investigate the sizes of condensation nuclei under different conditions. The question of variation in the size of the nuclei has been the subject of much discussion, but no method of making measurements appears to have been hitherto available.

Titration Curve of Vitamin B_1

THE titration curve technique furnishes a convenient method of studying the constitution of ionisable organic compounds the possibilities of which seem to be insufficiently appreciated by many organic chemists. From one relatively simple operation, information can be obtained as to the combining weight, the number of acid and basic groups in the molecule, and their several dissociation constants. With the aid of the 'formaldehyde curve' method, it is possible to identify which of the various pK values in a given complex ampholyte, acid, base or salt relate to amino, carboxyl or hydroxyl, or sulphydryl groups[1]. These measurements can be done on a very small amount of material, for example, no more than a milligram or so when dealing with a substance of the molecular dimensions of vitamin C^2 or B_1.

Our first observations on vitamin B_1 were made with a crystalline specimen of the dihydrochloride kindly provided by Prof. B. C. P. Jansen in 1931, and more recently we have examined also specimens of a higher degree of purity obtained in 1934 through the courtesy of Prof. Jansen and of Prof. R. A. Peters. Essentially similar results were obtained on all specimens, whether derived from yeast or from rice polishings. This supports the view that the crystals represent the vitamin itself in a substantially pure state.

The vitamin dihydrochloride at dilutions around $M/20$ in water has a pH value of approximately 3.

On titration with alkali, the curve of a group with pK value of 4·9 is the first to appear. The combining weight of the vitamin dihydrochloride, determined from the amount of alkali taken in the neutralisation curve of this group, is 330 ± 3 per cent. This is in good agreement with 337 for $C_{12}H_{16}ON_4S\,2HCl$[3], but does not agree with 355 for $C_{12}H_{18}ON_4S\,2HCl,H_2O$ or $C_{12}H_{18}O_2N_4S\,2HCl$[4], or 357 for $C_{12}H_{20}O_2N_4S\,2HCl$[5].

On continuation of the titration with alkali, a further curve is reached with pK value of about 9. This curve, however, takes approximately twice the alkali titre of the first. Its most striking peculiarity is that equilibrium is only slowly attained. After each separate addition of alkali the pH undergoes a sharp rise, but then gradually sinks again to a more acid value, equilibrium not being reached until 10–15 minutes. A corresponding slow change in equilibrium to a more alkaline reaction is encountered during subsequent back titration with hydrochloric acid. These observations point to the presence in the molecule of a distinctive 'pseudo acid' arrangement which is transformed to a labile acid group under the influence of alkali. Such pseudo acids are already known to exist in certain synthetic compounds in the pyrimidine and allied series[6].

On back titration with hydrochloric acid it is found that the titrable *amount* of the $pK9$ group has diminished as a result of the action of the alkali. Even in a titration carried out at room temperature, a loss of 10 per cent or more may occur, depending on the length of time the solution is permitted to remain at the alkaline reaction. This finding suggests that the variations which have been noted in the biological activity of different specimens of vitamin B_1 obtained by different workers may be due (as previously hinted[7]) to a variable degree of inactivation brought about through contact with alkali.

In presence of a solution of 5 per cent formaldehyde the pK 4·9 curve undergoes a slight shift to a more acid reaction. The magnitude of the shift is less than that to be expected for a primary amino group. The labile group at $pK9$ is not appreciably affected by formaldehyde. This finding is in keeping with the earlier belief that vitamin B_1 activity does not involve presence of an NH_2 group[8] (cf. Williams's formula[9]).

We are able to add that conclusions somewhat similar to the above have been reached by Ogston and Moggridge[10], who have kindly informed us of their results prior to their publication, and to whom we communicated our earlier findings.

Our detailed results will be published later, and observations are proceeding on the behaviour of certain scission products of the vitamin and of a number of synthetic analogues.

Critical Phenomena in the Oxidation and Self-Inflammation of Hydrocarbons

IN 1933 Townend and Mandlekar[1,2,3] discovered a new phenomenon in the self-inflammation of mixtures of air and hydrocarbons. They showed that on reaching a certain pressure there was a sharp reduction (100–200° C.) in the inflammation temperature. Similar effects occur in oxygen mixtures[4,5,6].

Townend and Mandlekar considered that the data were insufficient for drawing a final conclusion as to the character of the above-mentioned phenomenon, and advanced a tentative hypothesis in which ignition in the higher temperature range was considered to pertain mainly to the thermal decomposition products of intermediate compounds (probably aldehydes), ignition in the lower temperature range would occur when temperature and pressure conditions favoured the survival and further oxidation of those bodies.

An alternative explanation has occurred to us in which, in addition to the direct oxidation $A \rightarrow B$ (1) with velocity w_1 there is a reaction which proceeds catalytically with a velocity w_2 according to the equation $A + X \rightarrow B$ (2) where X is the catalyst. The velocity w_1 of the first reaction depends upon the temperature

$$w_1 = ae^{-E_1/RT}$$

X is an intermediate product of the oxidation and is formed in a reaction differing from the first in that:

$$A \xrightarrow{k_1} X \xrightarrow{k_2} B \qquad (3)$$

The maximum concentration of X depends on the ratio k_1/k_2 and it is natural to suppose that this ratio, and with it $[X]_{max}$, decreases, with increase of temperature. As a rough approximation we may assume that

$$w_2 = k\,[X]_{max}\;e^{-E_2/RT}$$

It is clear that the reaction velocity w_2 will be very small at both low and high temperatures on account of the smallness of $e^{-E_2/RT}$ and $[X]_{max}$ respectively in the two cases. However, over a temperature range between these two limits, w_2 may be relatively large.

If the above hypothesis is correct, the velocity of oxidation of the hydrocarbon, $w = w_1 + w_2$, should increase rapidly with temperature over a very wide range of pressure, and should then pass through a maximum into a region where there is a negative temperature coefficient. On still further increase of temperature, the velocity w becomes more and more dependent upon w_1 alone, and should again increase according to Arrhenius's equation.

In order to test the above hypothesis, the velocity of oxidation of pentane in mixtures containing $C_5H_{12} + 8O_2$ was studied in quartz vessels at various pressures below the ignition limit over a temperature range 300°–500° C.

The velocity is represented by $1/t_{50\%}$, where $t_{50\%}$ is the time in minutes during which the pressure rise reaches half its maximum value. At low temperatures a fairly large period of induction is observed, after which there is a rapid reaction accompanied by chemiluminescence. Up to 337°–345° C., as is evident from the experimental curves given in Fig. 1, the reaction velocity increases rapidly with temperature in all cases up to a sharply defined maximum. In the

temperature interval from 350° to 500° C, the velocity increases very slowly and then, above 500° C, rapidly again, so that for example at $P = 20$ cm and $T = 562°$ C, explosion takes place after a period of induction of 7 seconds The shape of the curves is similar at quite different pressures, and it is natural to draw the conclusion that with increase

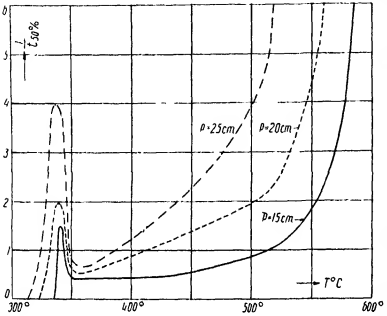

FIG 1

of pressure we should observe two regions of thermal ignition—at low (c 300° C) and at high (above 500° C) temperatures These have in fact been observed for a series of hydrocarbons by Prettre, Dumanois and Laffitte[6] and by Townend and Mandlekar and others

Fundamental Dimensions of Electric and Magnetic Constants μ_0 and K_0

THE letter from Prof. Wilberforce in NATURE of February 16, criticising my letter in the issue of January 19 on the above subject, shows me clearly that the system introduced into the teaching of dynamics and physics by Prof. Wm. Stroud more than fifty years ago, of allowing all the symbols in equations to contain their own units, is not so well known as I assumed or as it ought to be. This is clearly proved in the introductory paragraph; referring to the dimensions of μ_0 and K_0 Prof. Wilberforce writes: ". . . these dimensions, and not merely the numerical values of the quantities, are both completely arbitrary, depending upon the units of measurement which may be selected".

The Stroud system is fully described in a paper which I read to the Educational Section of the British Association at the Liverpool meeting in 1923, published in *Engineering* of September 28 of that year An example will illustrate its main features The dynamical equation $f = ma$ is a definitional equation defining force, and according to Stroud each symbol contains its own units and dimensions, the equation is true in all units if only the units are written down with the numerical values when these are known For example, a train of mass 100 tons acquires a speed of 60 miles per hour in 5 minutes, what is the average force? $f = 100$ tons × 60 miles/hour/5 min If the force is wanted in tons weight, one ton wt = 1 ton × 32 ft/sec² Whence, dividing one by the other and cancelling dimensions, we get $f = 11/12$ ton wt.

The Stroud system has been applied by him and others to all branches of physics and enables one to treat the science in symbols without reference to units, as I have done in my letter In electrical science, for example, $f = ee'/K_0r^2$ is a definitional equation defining electric charge e, and K_0 is a dimensional constant, which is assumed to depend solely upon the medium, it covers therefore our ignorance of the mechanism by which the force is transmitted The charges e and e' can be in ampere-hours, coulombs, C G S E S or E M units, electronic charges or any other units, provided these are written down with their numerical values The same applies to all other equations, hence it provides a means of discussing problems in the science such as, "the fundamental dimensions of μ_0 and K_0", irrespective of systems of units It is as easy to work in electrons and 'magnetons' as in c.g s or any other units Hence the natural system of units which Prof Wilberforce presents does not influence any of my conclusions.

I notice that Prof Wilberforce heads his letter "Dimensions of Electric and Magnetic *Units*", whereas mine was headed "Fundamental Dimensions of μ_0 and K_0 in Electrical Science". I hope that this is the cause of the difference of opinion between us and that now it is clearly stated, he will agree with my deductions

JAMES B. HENDERSON.

Do Whales Descend to Great Depths?

DR. F. D. OMMANNEY, in his letter in NATURE of March 16 (p 429), is of opinion that whales cannot descend with impunity below very moderate depths. In his "Discovery" Report on "The Vascular Networks of the Fin-Whale" he limits their normal dives to about 130 ft. and now, in his letter, to 35 fathoms or 210 ft

Old-time whalers, like Scoresby, experienced in the capture of whales by means of rowing boats and hand harpoons or simple gun harpoons, were of the opinion that Greenland whales and certain other whales, when harpooned and trying to escape, do descend to much greater depths and this, except for a temporary exhaustion, without being any the worse

As may be gathered from what Scoresby says, the whalers were of this opinion for a number of very good reasons

(1) The amount of whale line which had to be coiled into the whale boats, in different localities, depended on the depth of the water

(2) In deep water, when a whale 'sounded', or tried to reach the bottom the amount of whale-line it 'took' or drew out was limited and was obviously in proportion to its size and diving powers

(3) When the whale was 'sounding' and drawing out the line, the 'fast boat' behaved as if it was going right down it remained in about the same place

(4) After an interval, the whale reappeared near where it went down, and was easily harpooned a second time by one of the other boats Even a whale that had exhausted all the line in the 'fast boat and was 'loose' or free to escape, came up near where it went down

(5) In deep water, unless I am mistaken, a whale cannot be captured by means of floats or drogues'

A whale was certainly in an exhausted condition when it first came up after a long and deep dive, but if given time and not quickly attacked a second time, it soon recovered and broke loose, to be caught perhaps at some later date with the old harpoon still buried in its blubber At the Greenland Sea and Davis Strait fisheries, many whales were lost through negligence on the part of the nearest assisting boat quickly to 'strike' a whale a second time

In reply to the practical part of Dr Ommanney's letter, I would say that a long submergence is not necessary to permit a whale even when embarrassed by the harpoon and the whale-line to descend to and return from a depth of a mile In the case of whales that did not try to escape by 'sounding', the line taken out was not limited or definite in amount Among ice it was always much more In 1895 in the Greenland Sea, the *Polar Star* of Dundee lost a whale with 3,000 fathoms of line—all attached to a 'first harpoon'

There is, I think, no reason why whales should suffer from the troubles which affect divers and caisson workers[1]. There is not enough air in the whale's lungs to produce bubbles of nitrogen in the blood, even if this were mostly absorbed on going down to deep water, and the whale then came to the surface To produce bubbles on decompression, the whale would have to come up, fill its lungs and then go down until the nitrogen in the lungs was absorbed and repeat this operation, so charging itself with dissolved nitrogen. It is most unlikely to do any such thing.

It has been suggested that the lungs fill with water in the depths, and are emptied of water when the whale spouts. But I have come across observations which showed that the spouting took place in a very few seconds, and therefore emptied only the entry of the breathing passages It is most unlikely that the whale would have to spend time on the surface emptying its lungs of water How far the air in the lungs can be compressed depends on the anatomical arrangements and it is this which must control the depth to which the whale goes

Diet of Seals

In a letter in Nature of March 23 (p 473), Mr R W Gray says that there seems to be very little scientific evidence beyond that given by Mr G A Steven on this subject, and he objects to the validity of a generalisation on a basis of a study of only three specimens

In the past five years, I have examined four seals caught in the River Tay and have found the stomachs and intestines to contain the remains of fish These included immense numbers of flatfish, sprats and some salmon smolts In addition, there were great numbers of small crustacea, but most of them were forms well known as gill parasites of fish

Incidentally, tolerance and preservation of seals on the southern coasts of England may have had not a little to do with the disappearance of salmon from rivers in that area

Nova Herculis, 1934

The light curve of this nova continues to be abnormal after oscillating between 2^m and 5^m during the months January to March, the star has faded rapidly during the first half of April to 10^m on April 14 At the same time, the spectrum has altered, the chief new lines being due to [Fe II], represented by emission maxima displaced to the violet The two maxima previously present in H, [O I] and Fe II can now be seen only in the hydrogen bands These have faded along with the continuous spectrum, and on April 15 much the strongest line in the spectrum was [O I] 6300, the spectrum now consists predominantly of the forbidden lines of [Fe II], [N II] and [O I], resembling in many respects that of η Carinae

Word-Association Tests of Trance Personalities

This method of investigation[1] has recently been continued and extended with the following results

1 In a special experiment by Besterman and Gatty, the latter, acting as subject, was tested alternately in two 'poses' or 'orientations of mind' based on different aspects of his own life No attempt was made to give different reactions to particular pre selected words; but, in spite of this, *significant differences* were found between the two states, as regards both reaction time and reproduction test

It follows that such differences are not, as I had

at first supposed, evidence *per se* of the autonomy of the personalities compared

2 Using the term 'controls' to denote trance personalities specifically associated with the medium, as opposed to 'communicators' which are specifically associated with the individual 'sitter', I find that there is a significant tendency for controls to show, in respect of reaction time, the equivalent of a negative correlation—which I am terming 'countersimilarity'—when compared with other personalities Thus, of 10 comparisons involving 'Feda' (Mrs Leonard's control), 8 give a negative and 2 a positive result, while of 12 comparisons not involving Feda only 1 is negative and 11 are positive The chance of this disparity being fortuitous is less than 1 in 2,000

The same tendency is observable with 'Uvani' (Mrs Garrett's control) though to a lesser extent corresponding to the smaller quantity and inferior quality of the material available

This curious phenomenon seems explicable only on the assumption that 'Feda' and 'Uvani' are true secondary personalities formed round nuclei of repressed material The fact of repression seems calculated to produce in respect of certain words a longer reaction time for the normal than for the secondary personality, and probably vice versa, thus affording a basis for the inverse relationship observed

Since the effect is not found in the case of communicators, it would appear that these, if they are to be regarded as modifications of the medium, are of a different type from controls and formed in a different manner On the assumption that their claim to autonomy is ill-founded, they would seem to be more in the nature of histrionic poses than secondary personalities in the pathological sense

3 Normal persons, controls, the Gatty poses, and the one 'automatic' state hitherto examined—a total of 10 personalities—agree in showing, subject to very minor qualifications, a significant association of prolongation in reaction time with disturbance in reproduction This indicates that these diverse kinds of state—whether normal, secondary, 'posed', or of a presumably dissociated character—are at least 'undivided' in the sense that a single source is responsible for both times and reproductions

This is not true in the case of two out of the three communicators studied In each of these, one set of reactions is indistinguishable from those of the normal medium—the other, equally well defined, is significantly different There is accordingly a strong suggestion to the effect that two factors are here at work, of which one, if not extraneous altogether, is derived from some state or level of the medium's mind other than the normal, despite the fact that it is contemporaneously operative with it

The third communicator shows the association between reaction time and reproduction which indicates an undivided personality, but in this case there is no significant similarity to the normal medium in respect of either component, though only one (reproduction) is significantly different Probably the minimum straining of the evidence is required by supposing that this personality has achieved in both respects a separateness from the normal medium—of whatever kind this may be—which the other two have achieved in one respect only. Alleged Anæsthesia Produced Electrically

MR F. DE LA C CHARD, in defending the electric 'stunning' of animals[1], states that it is "only a matter of time before , research confirms the opinions expressed by eminent physiologists in favour of electric anaesthesia for animals" By thus prejudging the issue, Mr Chard illustrates the very attitude against which my letter was a protest

Mr Chard adds some sweeping generalisations One is that "Animals are very much more susceptible to electric shock than humans" In the systematic researches of such workers as Kouyvenhoven I can find no evidence to justify this statement. He also claims that unhealthy subjects are less susceptible to electric effects than are healthy ones, but Jellinek, a leading authority on electrical accidents, holds the contrary view[2] He claims also that "In electrical accidents, severe burning has been felt only as a stinging sensation'" But in other accidents severe pain has been felt The results of accidents vary so widely, according to the many variable factors concerned in them, that no such generalisation is worth consideration

Mr Chard's reasoning leads him to one conclusion that can be definitely tested by experience and proved to be wrong He concludes on theoretical grounds that the "A C is twice as effective as the intermittent D C used by Regensburger" But Regensburger produced exactly the same effects that are got in the slaughterhouse with A C , that is to say, when his current was too weak the pigs recovered too quickly and when it was too strong the reactions were too great for commercial requirements The point that Mr Chard has overlooked is that the rate of change of the current is an important factor as well as the amplitude

The real point at issue is that electric 'anaesthesia' has been pronounced genuine on the strength of two tests (i) absence of response to pain stimuli, and (ii) absence of pupil reflex Hertz's experiments have proved that these tests are not valid in the case of electric immobilisation, and we are therefore without any means of knowing whether, or at what stage, insensibility supervenes My letter was a protest against attempts to short circuit the need for knowledge

Newton and Spinoza

WITH regard to the new biography of Isaac Newton by Prof More and to the review in NATURE of January 5 (p 3), the following considerations may be of interest Brought up in a family devoted to the Royalist cause, Newton became a staunch Whig As a fellow of Trinity College he is said to have been influenced by the Platonists, but in spite of this, Newton became a man of science who is far from Henry More's mystical Paracelsic ideas. We must ask how this astonishing development took place, even if we suppose that Newton's genius was essentially responsible for it. I believe that no biographer has yet pointed out the possibility of Spinoza's views having influenced Newton, for this

great Dutch-Jewish philosopher was the only one among the philosophers of the seventeenth century who may be ranked with Newton Oldenburg, secretary to the Royal Society, visited Spinoza at his residence at Rhynsburg in 1661 and was in correspondence with him from 1661 until 1665 and afterwards, 1675 76, concerning scientific, philosophical and theological problems It is known that Boyle was interested in Spinoza's view, and it is most probable that Newton too had some knowledge of Spinoza and his works The "Theological Political Treatise" (1670) greatly influenced English metaphysicians, for example, Locke It might have influenced Newton's political and theological views as well

Of still greater importance is the question of the sources of Newton's scientific work If his thoughts about space and time were influenced by More, there is already a contact with Spinoza, because Spinoza may also have been influenced by More (see Prof L Roth's 'Spinoza", p 70, Ernest Benn, Ltd , 1929) But there is a great difference between the mysticism of the Platonists and the definiteness of Spinoza and Newton In their conception God is not hidden in Nature, for they sought to find Him there, the universe is for them rational We find in Newton's thoughts the same monistic and deterministic characteristic traits as in Spinoza's For both, philosophy and science are impersonal statements of impersonal truth The geometrical demonstration of Spinoza's "Ethics" (1677) is an expression of this impersonality, and I suspect that the deductive form of the "Principia" (1687) is derived rather from the "Ethics" than from Euclid In the 'Principia", and also in the "Queries" of the 'Optics", there are passages which seem to express pantheistic ideas Certainly there are other passages which may express an opposite point of view, but it is well known how great the prejudices of the time were and that Spinozism was regarded like atheism, and was therefore persecuted

Prof More has studied all the documents regarding to Newton, and as he does not say anything about Newton's connexion with Spinoza, there seems to exist no written proof We may suppose that Newton himself would have destroyed all documents or that his first editors tried to efface all evidence of a damaging relationship

Points from Foregoing Letters

PROF W ROWAN and Mr J Gregson report that the disease-carrying tick, *Dermacentor andersoni*, which hitherto refused to feed upon rabbits during winter, was induced to do so when the host was 'modified' by previous gradually increased illumination

Chicks fed upon a special diet developed a deficiency disease leading to changes in the gizzard, and to anæmia and hæmorrhage The disease was cured by foodstuffs like hog liver fat, hemp seed and certain vegetables Mr H Dam considers that these contain an essential new vitamin K This cannot be identical with the already known vitamins A and B, since fish-oils, which contain both these vitamins, do not cure the disease Mr F Schönheyder describes the tests used in determining the change in the clotting time of the blood of plasma of diseased chicks These tests serve to estimate the quantity of vitamin K present

The ability of neutrons to render silver radioactive has been shown by Messrs Herszfinkiel, Rotblat and Żyw to be increased by passing them through heavy water, though to a less extent than by passage through ordinary water (Fermi effect) A small increase in the thickness of the heavy water layer leads proportionately to a greater activity than in the case of ordinary water, and this is attributed to the fact that neutron-scattering takes place backwards in heavy water and forward in ordinary water

Although the anti-beriberi vitamin B_1 was the first vitamin to be discovered, its chemical composition and structure are still uncertain Drs T. W Birch and Leslie J. Harris, from the change in the intensity of acidity-alkalinity (*p*H) upon addition of alkali to a solution of the purified vitamin, calculate its molecular weight to be about 330 This agrees fairly well with the formula $C_{12}H_{18}O_2N_4S.2HCl$ They also find evidence for the presence of an atomic arrangement that changes under the influence of alkali, and may be responsible for the variations in biological activity observed by different investigators.

The velocity of oxidation and self inflammation of hydrocarbons is of great importance in connexion with the combustion engine Prof M Neumann and Mr B Aivazov have determined the velocity of oxidation of mixtures of pentane and oxygen in order to test the hypothesis that the sudden increase in this constant, which occurs at a certain temperature and pressure, is due to an intermediary catalytical reaction They find, in accordance with expectations, a maximum velocity at 340° C

Sir James Henderson, replying to Prof Wilberforce's criticism of his treatment of the dimensions of μ_0 and K_0 in electromagnetic theory, contends that these dimensions are not arbitrary, and that this follows from Stroud's system wherein every symbol occurring in a physical equation contains its own units

In answer to Dr Ommanney's objection, Mr R W Gray recapitulates Scoresby's observations which have led him to infer that whales can descend to great depths, 700–800 fathoms (not 2,500 fathoms as stated in NATURE of March 16, p 429) Sir Leonard Hill expresses the opinion that whales need not suffer from caisson disease after deep diving as there is not enough air in their lungs to produce bubbles of nitrogen in the blood when the animals come back to the surface

Mr Whately Carington, having carried out, with normal and 'psychic' persons, further word-association tests (time taken to respond to a list of words and type of response) finds that the 'significant differences' which he had previously found between medium and control, are also shown by other people in different 'orientations of mind' He finds now a negative correlation between the time-reaction to certain words which the medium gives in normal and in the 'trance' state From this he deduces that 'controls' which speak through the mediums are secondary personalities formed round nuclei of repressed material

Research Items

Stone Structures in the Western Transvaal A number of stone structures ascribed to "the ancients" have been investigated by Dr. Ir E C N van Hoepen and Dr A C Hoffman (*Argeologiese Navorsing van die Nasionale Museum*, Bloemfontein, Dl 2, St 1) These structures are situated at Buispoort, 24 miles north-west of Zeerust, and consist of stone walls which have served for huts, enclosures around huts and for cattle There are also walls which served as storage platforms for grain bins, semi circular to nearly completely circular stone rings surrounding threshing floors, small structures for storing grinding stones, furnaces for smelting iron ore, heaps of slag, ash heaps and remarkable graves On the evidence of both Campbell and Moffat, and taking into account the reputation of the Bahurutsi for iron working, it is concluded that these structures are the work of the ancient Bahurutsi, especially as skulls found here are similar to recent Bahurutsi skulls from Braklaagte These structures corroborate and substantiate for the first time the fact that the Bantu did build with stone This has an important bearing on the problem of the Zimbabwe culture The graves found were all covered-in fissures between rocks Many bones show signs of burning, which may be due to their burial after a Matabili raid in which the houses with their occupants were burned A number of furnaces, without doubt for the production of iron, have been found Potsherds and two or three broken pots were found The material is coarse, and it contains foreign matter which does not improve the clay It was probably introduced without clear understanding of its operation in firing Three or four definitely globular pots were found These are rare among the modern Bahurutsi Pots with three legs had reached a culminating point, the legs being of enormous size A pot with a gradually thinning lip may have been introduced by strangers

The Manatees Not since Hartlaub's paper of 1886 has an attempt been made to monograph the manatees (genus *Trichecus*), and Robert T Hatt's contribution on the group in the "Scientific Results of the Congo Expedition" establishes a few hitherto unrecognised characters for the distinction of the crania of the different forms, corrects certain erroneous conclusions come to by Hartlaub, and records for the first time specific features of the post cranial skeleton (*Bull Amer Mus Nat Hist*, **66**, 533, 1934) While admitting only three living species of manatees, one African and two American, the author considers it probable that geographic extremes of these species are racially distinct. But the Congo specimens showed no character that could distinguish them from the better known forms from Senegal The African species (*T senegalensis*) is more closely related to the West Indian species (*T manatus*) than to the South American *T inunguis*, so that there seems to be a stronger linkage in this case between the distant African and West Indian species than between the neighbouring American species.

Bacterial Decomposition and Synthesis of Cellulose. Mme. Y. Khouvine, who has been responsible for much work on the decomposition of cellulose, has recently reviewed briefly the present position in this field (Actualités scientifiques et industrielles, 164 "Exposés de chimie biologique" (2) "Cellulose et Bactéries" Paris Hermann et Cie) In it she deals in turn with the chief aerobic, anaerobic and thermophilic bacteria that have been described as cellulose decomposers As in many other publications, the organism *Spirochaeta cytophaga*, first isolated by Hutchinson and Clayton in 1918, and known now as *Cytophaga Hutchinsoni*, is named as being the most numerous and active cellulose-decomposing organism in the soil, though, in point of fact, it has never been conclusively shown to be active in attacking the cellulose of plant residues It is a little unfortunate too that fungi are not dealt with as well as bacteria when considering cellulose-decomposition, for there is no doubt that under aerobic conditions the former group is of great importance The last part of the present useful little work is devoted to the consideration of the synthetic activities of *Acetobacter xylinum*, which when growing on sugar alcohols such as mannitol or sorbitol, produces acid, and on the surface a membrane now shown by Hibbert to be true cellulose The crystallites are not oriented as in a fibre, but by tension may be partially aligned so that an X-ray diagram is obtainable not very dissimilar from that of cotton. Details of the culture of this organism are given, and its fermentative reactions considered

Chromosome Homologies in *Drosophila* *Drosophila melanogaster* has four pairs of chromosomes while *D pseudo-obscura* has five pairs In the latter species, five linkage groups of genes have been found, and a further study of this species (Crew and Lamy, *J Genet*, **30**, No 1) indicates that snapt and tilt (wing characters) and sepia (eye colour) are located in the left arm of the *X*-chromosome, which corresponds in part with the right arm of chromosome III in *D melanogaster* On the right arm of the *X* are located eosin and cuprous The rod-shaped chromosome III of *D pseudo obscura*, which contains the dominant stubble and the recessive glass (eye), is found to be homologous with a considerable portion of the left arm of chromosome III in *D melanogaster* The mutations short and jaunty in the fourth linkage group of *pseudo-obscura* (a small rod-shaped autosome) may be homologous with part of the right arm of chromosome II in *melanogaster*. Thus it appears that there has been a considerable rearrangement of the chromatin material since these species diverged from a common ancestor The authors also discuss the nature of the action of the genes for eye colour, based on observations of colour changes during ontogeny and on the colour effects produced on eye and testis sheath by various gene combinations They conclude that these genes are not directly concerned in pigment production, but act on the mechanism which is responsible for production and deposition of pigment, the colour of the pigment being determined by the chemical conditions at the stage of development when the pigment is formed.

Malayan Orchids. A paper on "Some Malayan Orchids" appears in the *Gardens' Bulletin* of the Straits Settlements (8, Part 2, Jan 26, 1935). It is by Mr C E Carr, and describes the orchids collected by the Oxford University Expedition to Sarawak in 1932 The plants were obtained from

the neighbourhood of Mount Dulit, at altitudes varying from near sea level to 1,400 metres 132 species were collected, and 32 are now described for the first time Descriptions of the species are very complete, and lengthy diagnoses of new species appear in Latin and English A perusal of the descriptions suggests that many kinds will in the future, add even greater beauty to our already beautiful English orchid houses An attempt is made to describe the perfume of several species, and both the systematic botanist and the gardener will find a great deal of interest in the paper Members of the genera *Bulbophyllum*, *Coelogyne*, *Dendrobium*, *Dendrochilum* and *Eria* predominate in the list

Entomogenous Fungi. Mr T Petch has recently published further "Notes on Entomogenous Fungi" (*Trans Brit Mycol Soc*, **19**, Part 3, 161–194, Feb 1935) Having already described seventy five species of fungi which attack insects, Mr Petch continues with No 76, and his present paper finishes with No 100, but a very useful review of the entomogenous species of the genus *Cladosporium*, and the description of eight new species of fungi relieve its abruptness and make it complete in itself Eight species of *Cordyceps* are described critically, whilst fungi of this genus which attack orthopterous insects receive special mention The new species are *Blastotrichum aranearum*, on spiders, *Hirsutella radiata*, *H formicarum*, on ants, *Verticillium fuliginosum*, *Sporotrichum columnare*, *Metarrhizum brunneum*, *Patellina epimyces* and *Stereocrea coccophila* Most of the fungi are foreign to Great Britain, and many have been collected from Ceylon

Baluchistan Earthquakes of 1931 The recently issued part of the Memoirs of the Geological Survey of India (**67**, 1 82, 1934) contains an interesting study by Mr W D West on the destructive Baluchistan earthquakes of August 25 and 27, 1931 The district is one that is frequently visited by earthquakes, the most important predecessors being those of December 20, 1892, and October 31, 1909 Of the two recent earthquakes, the earlier and less intense, known as the Sharigh earthquake, occurred at about 3 5 a m, I S T (August 24, 9 35 p m, G M T) The epicentre was close to Sharigh and its focus was clearly shallow, for, though the intensity was 8 (Rossi-Forel scale) in the epicentral area, it faded away rapidly, so that the total area disturbed was only about 31,000 sq miles The second, or Mach, earthquake occurred on August 27 at about 8 57½ p m, I.S T. The epicentral tract was a long, narrow, curved band, following closely the strike of the rocks for about 100 miles in a general southerly direction from Mach Within this band, the shock reached the intensity 10, and caused much destruction to buildings The disturbed area covered a large part of Baluchistan and Sind and contained about 370,000 sq miles, or about the same as that of the Californian earthquake of 1906 The epicentres of both earthquakes were closely related to the re-entrant angle in the eastern boundary of the Baluchistan Hills, that of the Sharigh earthquake being on the northern side, and that of the Mach earthquake running parallel to the south-western side, of this angle

Use of Drilling Mud in Burma Oilfield. The search for new and deeper sources of oil in the fields of India and Burma has during recent years been complicated by heaving or caving shales and high-pressure water issues Laboratory experiments and field experience have shown that the former difficulty can be surmounted by selection of a drilling fluid from which there settles out, when mixed, a minimum of free water Also, to discourage penetration of formation water into the hole, the fluid must either be sufficiently heavy in itself to overbalance formation water pressure or failing this, it must be loaded with barytes, iron oxide, etc High pressure water issues, whether associated with heaving and caving or not, can be combatted only by application of sufficient pressure to counteract formation water pressure, this is done by the use of a loaded drilling fluid and back pressure supplied by the drilling equipment Mr A W G Bleek, in his paper "Some Experiences in the use of Drilling Fluids in the Yenangyaung Oil-field, Upper Burma" (*Trans Min Geol Inst India* **39**, 3, December 1934), after an exposition of these difficulties, proceeds to record personal observations made during the deepening of a well in the southern extremity of the Yenangyaung Field, Burma All previous attempts at deep drilling in the neighbourhood had failed, and records showed that, in the case of the present well, heaving and caving must be anticipated, also water lying between 4,800 ft and 4,900 ft was believed to be high pressure water Actually no high pressure water issues were encountered and the problem was, therefore, confined to prevention of heaving and caving and exclusion of formation water Back pressure drilling equipment was not called into operation though it was ready on site, and the successful deepening of this well is attributed to the use of a mud fluid which, while preventing heaving and caving, was possibly also responsible for the absence of high-pressure water issues, which are frequently attributed to poor quality fluid and consequent encouragement of flowing shales

Ozone in the Atmosphere. A R Meetham and G M B Dobson (*Proc Roy Soc*, A, March 15) have investigated the vertical distribution of atmospheric ozone in a high latitude (Tromsø, lat 69° 40′ N) The method used involves the measurement of zenith sky light at two wave lengths for various zenith distances of the sun, and it has already been applied in Switzerland, yielding results which were confirmed by Regener's sounding balloon measurements The height of the centre of gravity of the ozone is nearly the same at Tromsø and at Arosa, but the distribution is rather markedly different At Tromsø the ozone is more concentrated in a region about 21 km high, while in Switzerland it is more uniformly distributed through the lower 30 km

A New Form of Cloud Chamber. C T R Wilson and J G Wilson (*Proc Roy Soc*, A, Feb 15) describe a new type of cloud chamber which possesses very interesting features and may be further developed In this chamber the flow of air when the expansion takes place is radial, the air leaving the chamber by slits left between flat rings of slate which are piled to form the walls of the chamber The corresponding distortion of the tracks is a uniform two dimensional magnification Both back and front of the vertical chamber are of glass, and the illumination is supplied through the back, the light being stopped out of the camera as in microscope dark-ground illumination Since the tracks scatter much light through small angles, the illuminating arrangement is very efficient Another important innovation consists in allowing

the chamber and its auxiliary gear to fall freely under gravity, it being released as the expansion takes place It is claimed that the chamber may thus be removed from a confined space, for example, the pole-gap of a magnet, before the photograph is taken. Since gravitational forces do not affect the contents of the chamber, convection currents are prevented and the tracks retain their form for a long time This may prove an important advantage for some types of work

Isotopic Water in the Sea. The densities of samples of water from different oceans have been found by H E Wirth, T G Thompson and C L Utterback (*J Amer Chem Soc*, **57**, 400, 1935) to be very uniform for the Mediterranean, Red Sea and Indian Ocean, with one exception of water obtained at 4,000 metres in the Indian Ocean, which gave the highest values ever found No surface specimen from this locality was available Low values were found for samples from the Antarctic, North Pacific and Bering Sea One result of the investigations was that regions of high dissolved oxygen content are those of low density, and conversely Waters from the Baltic showed low density differences from ordinary distilled water, which are attributed to dilution by land drainage, and a region of the San Juan Archipelago noted for its abundant fauna and flora yielded waters of low density differences The paper describes an apparatus for measuring small differences of density of the order of 10^{-6}, depending on the communicating tube method, the liquid heights were altered by means of metal plungers and an oscillation circuit was used

Element 93 The experiments on the bombardment of uranium with neutrons led Fermi to conclude that elements with an atomic number above 92 are formed (NATURE, **133**, 898, 1934) It was assumed that the product, with a period of 13 minutes, which is precipitated from a highly oxidising and acid solution along with manganese, is the highest homologue of the latter, or element 93 A V Grosse and M S Agruss, however, had expected other properties for this element, and they now describe (*J Amer Chem Soc*, **57**, 438, 1935 See also NATURE, **134**, 773, 1934) some experiments in which protactinium, the longest lived isotope of element 91, was used as an indicator in experiments similar to Fermi's Manganese dioxide and rhenium sulphide were precipitated from uranyl nitrate and protactinium solutions The behaviour of element 91 and the reported behaviour of element 93 were found to be identical within the limits of experimental error The authors, however, report that Fermi has tested whether the artificial radioelement is precipitated with zirconium phosphate, the coprecipitation being a very clear and definite reaction for element 91, and has found that the active products are not precipitated, which speaks against identity with element 91

Properties of the Telephone Transmitter. The design of early types of telephone transmitter was almost entirely empirical In the commercial form, the electrical resistance of a small column of specially prepared carbon granules is made to vary by the sound waves which it is desired to transmit. In appearance the carbon granules are like granite chips, and the column consists of a series of sharp corners and edges in contact with more or less plane surfaces In the Engineering Supplement to the *Siemens Magazine* of March, it is stated that the Company, seeing that the limit of progress on purely empirical lines was practically reached, decided to attack the problem experimentally and theoretically, and appointed Mr G W Sutton to analyse the working of the 'Neophone transmitter' and to measure its mechanical and electrical properties if possible He describes in this supplement a new method of measuring these properties, and attempts to make a complete analysis of the 'Neophone' transmitter, which incorporates some of the latest developments The influx into the industry all over the world of a younger generation of engineers trained in the modern technique of acoustics and of audio-frequency engineering has enabled research work on a larger and more effective scale to be done The introduction of new raw materials and of improved factory processes has also helped The author has collected many experimental data which will be found useful Considering that the time permitted for the research was somewhat limited, the agreement between the calculated curve and the observed frequency characteristic is very good The demand for an improved quality of speech in telephone transmission probably arises from the education of the faculty of discrimination of the public by the gramophone and by broadcasting

Current Measurement at Radio Frequencies. At a meeting of the Meter and Instrument Section of the Institution of Electrical Engineers on April 5, Dr H E M Barlow read a paper entitled "A Valve Ammeter for the Measurement of small alternating Currents of Radio Frequency" This paper comprised a description of an alternating current milliammeter having four ranges, 5, 10, 20 and 30 milliamperes and suitable for measurements at frequencies from 25 cycles to 5×10^6 cycles per second The instrument makes use of a two electrode thermionic valve, with its direct current supplies arranged to give the saturation current in the anode circuit Under these conditions, if the temperature of the filament is raised by a small amount, a rapid increase takes place in the saturation current Thus if an alternating current is superimposed on the direct current through the filament, the increase in the anode current provides a measure of the alternating current In the first arrangement of the instrument described in the paper, suitable filter circuits are included to restrict the alternating and direct currents to their appropriate paths A simple resistance-bridge arrangement is connected in the anode circuit, by means of which the steady current through the galvanometer is balanced out On the application of alternating current the balance of the bridge is upset, and the deflection of the galvanometer indicates the value of the current to be measured An alternative arrangement of the instrument employs a second valve so connected in the circuit that any drift of the galvanometer zero, due to variation of filament battery voltage, is avoided Among the advantages claimed for the instrument are that it is sensitive and quick in response, that several ranges can easily be incorporated in one instrument, and that it has a high overload capacity. A typical calibration curve for an instrument having a range of 5 milliamperes is included in the paper, and shows that the accuracy of indication is within 0·5 per cent from 25 cycles per second up to nearly 5 megacycles per second.

Fruit Soil Survey

THE county of Kent, along with its neighbours Surrey and Sussex, became classical ground for the scientific survey of soils after the publication of "A Report on the Agriculture and Soils of Kent, Surrey and Sussex" by Sir Daniel Hall and Sir John Russell. Now, more than thirty years after that auspicious pioneer work, a "Survey of the Fruit-growing Areas on the Lower Greensand in Kent" has been published by the Ministry of Agriculture and Fisheries (Bulletin No 80. Pp 81 H M Stationery Office, 1934 3s net) The Survey reports extensive work by Messrs W A Bane, of East Malling Research Station, and G. H Gethin Jones, of the South Eastern Agricultural College, Wye, and collects the results of a large number of observations

It is only by the application of intensive methods of soil survey to small areas that they can be made of use to the practical grower This has been done in the survey under review, and as a result, twenty six types of soil have been recognised Of these, only about six are regarded as naturally good for the growth of fruit, though others are classified as average or fairly good Good soils cover extensive areas Estimation of the suitability of particular soils for the needs of a particular crop is not easy, but the survey under review takes into account such factors as soil water, drainage and the less tangible effects of such features as management.

The solid geology of the district is illustrated by a coloured map inserted in the Bulletin, and by a very useful diagrammatic section, in addition to descriptions in the text Methods of soil classification are based upon the American method of field examination Soils which have the same geological origin, similar water relations and profile, and analogous topographical position are placed in the same series Each series is subdivided into types according to the texture of the surface soil, and each type may have one or more 'phases', according to variation in such features as depth or drainage

Several valuable conclusions emerge from the report The area of Kent covered by the Lower Greensand is undoubtedly very suitable for the growth of tree and bush fruit Water conditions of soils in this area seem to determine their suitability for fruit growing, rather than physical nature of the particles The question of draining is dealt with in an interesting manner, and it is shown that two soil series known as the Malherbe and Cox Heath are both troubled by excess of water in winter The Malherbe series can be improved, by draining, for a certain type of fruit growing, whilst it is "doubtful whether the cost of such work would be repaid on the Cox Heath series" Heavier soils derived from the Folkestone sand strata can be used for fruit growing, if careful manuring, particularly with potash, is performed Lighter soils from the same strata cannot be improved profitably

Soil survey has been correlated carefully with the use of such special practices as ringing, and studies of varying root systems in different soils and on different rootstocks open up interesting possibilities for future work The survey of existing fruit plantations reveals the fact that a large proportion contain apple trees which are unsuited to modern needs, are grafted upon rootstocks unsuited to the type of crop desired, and are not spaced to the best advantage

There can be no better advocate of improved cultivation than the presence of East Malling Research Station in the area under survey Results from this Station are of the highest practical value, and indicate, among other things, that fruit of dessert quality might be grown more extensively in the area, rather than that of culinary grade as at present The Survey is already welcomed by the more progressive trade organisations as a valuable contribution to the age-old industry of fruit-growing.

Pygmies of Central Africa

THE difficulty of placing the pygmies of Central Africa in such a position in a scheme of ethnological classification as will be generally accepted as convincing is well known To a certain extent this is due to the lack of adequate detailed information bearing on their physical characters; but in part it also arises from the fact that such material as has been available did not readily admit of comparative study of variation among the pygmies themselves This applied especially to the question of the degree to which they were related to, or showed evidence of admixture with, the peoples of greater stature, the negroes, among whom they had their habitat.

It was, therefore, welcome news to anthropologists that Paul Schebesta, who had made a study of the pygmies of the East, and more especially of the Semang of the Malay Peninsula, was undertaking an expedition to the Congo for the purpose of studying and measuring the African pygmies

P Schebesta's expedition was in the field in 1929–30. It was made possible by the generous assistance of the Charles University, Prague, the Comenius University, Bratislava, and a contribution was received from the Dr Aleš and Mrs. Marie Hrdlička Fund The material collected has been analysed by Prof Victor Lebzelter, who had dealt similarly with the Semang material collected by P Schebesta, and the combined report has been published by the Czech Academy of Sciences and Arts*, the tables of original measurements being included and an English translation appended

In the first section of the report, P. Schebesta deals with the demography and morphology of the pygmies, the anthropological analysis by Prof Lebzelter forming the second part The peoples or groups who came under observation fall into two categories—the pure pygmies of the Ituri Forest region, who are distinguished by special somatic features, and the pygmiforms—a term here preferred by the authors to 'pygmoid', as this latter term is generally used to include peoples who approach the

*Česká Akademie Věd a Umění (Académie Tchèque des Sciences et des Arts) Třída (Class) 2 Anthropologica Anthropologie Středoafrických Pygmejů v Belgickém Kongu (Anthropology of the Central African Pygmies in the Belgian Congo) Napsali P Šebesta a V Lebzelter Pp 143+66 plates. (Prague Česka Akademie Věd a Umění, 1933)

pygmies in their small growth only The pygmiforms, while presenting racial features of the pygmies which are absent in the pygmoids, differ from the standard pygmaean type without being negroes Some of the pygmiforms approach the standard pygmy closely, others differ widely The pygmiforms, or mixed types, are already to be discerned on the periphery of the Ituri region, especially on its northern border The pygmiforms who came under the observation of the expedition were Batwa in Ruanda, the Baćwa, or Batembo, of the Province de l'Équateur north of Lake Leopold II, and sedentary or village Basúa, so-called, who live in four villages within the Ituri limits

The Bambuti, the pygmies proper, of the Ituri are not divided into tribes, but for linguistic reasons, they fall into three groups on the basis of the negro languages they have adopted These groups are the Aká, the Basua and the Efé The Bambuti number in all about 25,000, distributed over an area of 123,000 sq km They are by no means on the decrease, though owing to the strenuous condition of nomadic life, infant mortality is high It would seem that the conditions of life are such that an approximate stability of population has prevailed for some considerable time The state of health of adults is excellent, and grey headed men and women are not rare

Though there is no race which at first inspection presents so many strange features as the Bambuti, there is no sign that they are a product of degeneration Though the body is remarkably short and clumsy, it is not stunted The average height for men is 146 cm and for women 133 5 cm The shortest woman measured was 118 cm She was the mother of six children Pygmy men of more than 150 cm are very rare

The heavy and clumsy appearance in build of the pygmy is due to the relative proportions of the body The head is disproportionately large, the neck short and the trunk disproportionately long Steatopygia is not marked The legs are short and thin and to a superficial observer suggest rachitis. The gait is heavy and clumsy, but in running swift and light-footed The knee shows marked projection of the patella The complexion in the more pure Bambuti is a greyish yellow The darker complexion, which is sometimes found, is probably due to negro admixture.

The conformation of the face is unique and in itself is sufficient to distinguish the pygmy from all other races Two types are recognised Of these one is long with a sudden narrowing of the lower part below the zygomatic arches, so that it ends in a pointed chin, the other is a round faced type, in which the cheek bones are less prominent and, probably, there is less prognathism The round projecting conformation of the forehead is striking It is especially noticeable, because there is almost no root to the nose The nose itself is very characteristic It is button shaped, and always broader than it is long It is a highly specialised form, for the study of which it was found necessary to devise a new technique The mouth is large and the lips thin Owing to the weakly developed receding character of the chin, the mouth has a markedly snoutlike appearance

The hair is either frizzled or spiral The latter is only half as frequent as the frizzled, but reliable data cannot be given as the Bambuti are mostly shorn There is a strong growth of face and body hair, but the growth of lanugo was observed rarely only, and then in women and only on arms and legs

There is very great variation in the details of the ear, and five types are distinguished It presents a general resemblance to negro or even European ears, but it differs fundamentally from the Bushman ear notwithstanding resemblance in certain features

There is evidence throughout the analysis of the anatomical data that in certain characters the pygmy is a highly specialised type Prof Lebzelter, in summing up his conclusions on the ethnological characters of the pygmies, distinguishes six types Pygmy Types I, II, and III, the Europoid Types, and Negro Types I and II Of the pygmy types, I and II are dolichocephalic and sub-dolichocephalic respectively, while III is brachycephalic with thinner lips and low face The Europoid Type is taller, with narrower face, narrow nose and thin lips, while Negro I is taller, with long skull, broad nose and thick lips and Negro II is brachycephalic, but otherwise has similar features

The distribution of these types shows that there are considerable differences within each tribe In the main, the Bambuti are of one race, with the addition of a small percentage of negroid and European elements

Research and the Library

By DR J L BERRY, Lecturer in Physiology, and DR. WILFRID BONSER, Librarian, University of Birmingham

THE enormous output of research to-day which finds its way into scientific and medical periodicals has produced a problem both for the research worker and the librarian The former finds it impossible to read everything now being published, and the latter finds the cost growing more and more prohibitive quite apart from the amount of shelf room required each year for housing

The recent campaign conducted in the United States and England against the exorbitant cost of German scientific and medical periodicals has resulted not only in a reduction in prices, but also in a reduction in bulk of the publications themselves. There has long been a well-founded complaint against the unnecessary amount of matter published, for the usual practice was to include in each article not only the original contribution to research but also a lengthy résumé of the whole subject, which was, or at least should have been, already known to readers The price reduction has been secured by the beneficial excision of this superfluous matter.

From our point of view, further reforms are necessary, and we put forward the following as conducive to clarity, economy of cost, bulk, and library storage room.

1 It has long been the practice of chemical journals to accept only new matter, and this cut down to the briefest account. This principle can be adopted with advantage in other scientific subjects The modern tendency of the young research worker to be judged upon the number of his papers rather than their quality swells the amount of printed matter. Ruthless editing of immature work and refusal of partial results of a research would lead to

the increased reputation of the worker which would be acquired by one complete and authoritative paper. Most journals do not make full use of their competent editorial boards, who must co-operate with the contributor and the publisher to attain this desirable objective

2 Much space is occupied by a long list of references to previous authors, and many of these can be eliminated by a single reference to what we term a 'key paper' Where a good paper on the subject with a full historical bibliography has already been published (for example, in *Physiological Reviews*, or a monograph) this could be quoted in lieu of repetition, papers subsequent to this only being cited Such 'key references', in these days of specialisation within subjects, inflict no hardship upon the interested reader and would avoid the full list of references being given every time

The 'key reference' would reduce the long preamble setting forth the reasons for undertaking the particular line of research, and would yield a concise statement of method and results

Failing a ready made 'key paper', the complete and authoritative paper previously mentioned would thereupon automatically become the 'key paper' on that particular subject

3 Abstracting journals are published mainly in English and in German, and it cannot be claimed that both are essential Where a full abstracting service is available in one language (for example, in the *Ber ges Physiol*) this should adequately cover the field and absorb or replace all others It is no longer a valid excuse that German is not known by English speaking workers, as a working knowledge of both languages is part of a scientist's equipment

If a full abstracting service does not exist for a subject, we recommend the excellent system adopted by the Royal Microscopical Society, which publishes, as an appendix to each part of its journal, abstracts from articles appearing in other journals on cognate subjects If this practice were made a general one, a saving in bulk and binding would accrue For example, the Physiological Society by printing its abstracts in the *Journal of Physiology* might (although slightly enlarging the size of the journal) eliminate its second periodical, *Physiological Abstracts* If the Society did not adopt this procedure, which we term 'telescoping', it might save space by excluding all abstracts from articles in its own *Journal of Physiology*

4 'Telescoping' could usefully be employed in removing redundant publications. The *American Journal of Physiology* could coalesce with the *Journal of General Physiology*, the gain being the heightened standard of the articles

Some societies, including the Royal Society of Arts and the Royal Society of Medicine, print papers *in extenso* in their journals when a résumé would usually be preferable: they also print *verbatim* the vote of thanks proposed by the chairman (the inclusion of which is tedious and unnecessary), as well as the ensuing debate. Excision of these would reduce the journals in question from unwieldy tomes to volumes of handy size.

The instructions for the reduction of bulk which were issued by the firm of Springer for their periodicals have already been abstracted in NATURE[1]: these might serve as a model in Great Britain and the United States.

[1] NATURE, 132, 34, July 1, 1933.

University and Educational Intelligence

COLLEGE HALL, London, founded in 1882 to provide residential accommodation for university women students, has been greatly enlarged in the past four years Its recently issued annual report includes a detailed account of the opening of the "Mary Brodrick" wing by H R H Princess Alice on November 15 With this addition, the Hall is able to house 172 students It fulfils an important imperial and international function in facilitating social intercourse between students from different parts of the Empire and from foreign countries Its financial stability is, for the present, assured, but there is still a substantial debt to be cleared off, and the Council is especially anxious to do this at the earliest possible date so that it may increase the number of rooms let at reduced rates to impecunious students and build up a reserve fund for the purchase of the freehold of the site.

SECONDARY school problems in the United States are discussed in an article by Prof D Snedden, of Teachers College, Columbia University, in *School and Society* of February 16 The four-year high school, he says, tends rapidly to become a school for the whole of the population (9 millions) between 14 and 18 years of age Already in 1934 two thirds of this population was in full time attendance Except as regards what he calls their pseudo-vocational courses the high schools are still excessively under the spell of college entrance requirements Changing family and economic conditions render increasingly profitless any serious vocational training begun before the age of eighteen or twenty years, and such vocational education as the high schools can offer is practically valueless Hence an urgent necessity for devising high school curricula that shall enable these vast armies of pupils to be adequately prepared for finding themselves amid the modern world's welter of products of printing press, camera, phonograph, laboratory and shop A few suggestions are offered, starting from the assumption that there must be at least three parallel sets of courses for the exceptionally gifted, the average, and the sub average pupil

THE Carnegie Trust for the Universities of Scotland held its thirty third annual meeting on February 6 Among the outstanding events of the past year the report records the death of Lord Sands, its chairman since 1922, when he succeeded Lord Balfour of Burleigh His place has been taken, since last July, by Sir H Arthur Rose Grants to universities and extra mural institutions are distributed by the Trust quinquennially, the last distribution, for 1930-35, having allocated £259,025, to be spent on libraries (£29,725), buildings and equipment (£184,600), and endowment of teaching and other general purposes (£44,700) Of the Trust's activities under its scheme of post-graduate study and research for 1933-38, the report observes that since awards were intimated last July, there have been many resignations on account of acceptance of salaried posts—a sign, it is hoped, of improved economic conditions in the country. Assistance in payment of class fees for 1933-34 absorbed £56,348, the number of beneficiaries being 4,017 Forty former beneficiaries voluntarily repaid to the Trust during the year sums amounting in the aggregate to £1,658, including a remittance of £300 from one whom the Trust had assisted to the extent of £100 only while he was a student in 1902-6

Science News a Century Ago

Sir Charles Bell on the Brain

On April 30, 1835, Sir Charles Bell continued the reading to the Royal Society of his paper on the relation between the nerves of motion and of sensation and the brain The report of his paper said "The author enters into a minute anatomical investigation of the structure of the spinal cord, and of its relations with the encephalon, and with the origin of the nerves He finds that the spinal cord is constituted in its whole length, by six pairs of columns, namely, two posterior, two lateral and two anterior, each column being composed of concentric layers, and invested with an external coating of cineritious substance, and all the columns being divided from each other by deep sulci, which penetrate nearly to the centre of the cord On tracing the posterior columns in their ascent towards the encephalon, they are seen to diverge laterally at the *calamus scriptorius*, or bottom of the fourth ventricle, and to proceed into the substance of the cerebellum "

Quetelet's Natural Philosophy

Among the "Analyses of Books" contained in the *Records of General Science* of May 1835 is a notice of the "Facts, Laws and Phenomena of Natural Philosophy etc Translated from the French of Professor Quetelet of Brussels, with notes by Robert Wallace"

"For this translation," the notice ran, 'we are indebted to the industry of some young ladies in the vicinity of Glasgow Mr Wallace, the editor, states that having been called to give some lessons to some young ladies who were desirous of acquiring a knowledge of Natural Philosophy, he proposed that he should employ M Quetelet's work as a text book This proposal was adopted, the work translated, and the result of their labours is now presented to the public. It is extremely gratifying to see the tender sex not only enriching our books of science with their pencils, but actually studying something more than mere superficialities M Quetelet is concise in his statements of facts, of which the work forms a good digest Tho recent important discoveries in electricity of Dr Faraday have entirely escaped the notice of the author, but should have been introduced by the editor, as they include some very curious phenomena and constitute a very essential part of the science"

Gurney's Oxy-Hydrogen Light

"Tho Bude Light," said the *Mechanics' Magazine* of May 2, 1835, "is a name given by Mr Gurney (of steam-carriage abortion celebrity) to a new light which he has discovered, and so named after his new place of residence in Cornwall It is obtained by directing a stream of oxy-hydrogen gas on a quantity of powdered egg shells The light is represented to be 140 times greater than any of those now employed in lighthouses—so intense, indeed, that Mr. G lately stated to the House of Commons Committee on Lighthouses 'his belief that it would be possible to make his light, by certain management, point out the precise situation of a coast beacon to a ship three or four miles at sea, under circumstances of a fog so dense that no other light—not even the sun—could penetrate it to any distance'!"

Tribute of Science to the Royal Jubilee

AMONG the addresses received by H.M. the King after his accession to the Throne on May 6, 1910, was one from the Royal Society, in which reference was made to the interest which His Majesty, when Prince of Wales, had continually shown in the progress of discovery and invention In consenting to succeed his father, King Edward, as Patron of the Society, King George expressed appreciation of these elements of national greatness, and assured the deputation of his "sympathy and support in your beneficent efforts for the promotion of natural knowledge" The collection of articles which appears in this special issue of NATURE, nearly all of which are by fellows of the Society, indicates some of the directions in which these efforts have been remarkably successful by adding new realms to the empire of science and conducting profitable explorations in them

Science, like the universe, has no natural partitions either in space or time; so that any record of its achievements cannot be limited to a particular period or country It happens, however, that the twenty-five years now being celebrated as the jubilee of the King's reign have seen a greater number of creative ideas in science than any corresponding period in the history of the world, and also that the contributions of British investigators to the rich harvest of scientific knowledge which has been gathered in are both distinctive and of supreme importance The articles outline some of the fertile fields of research opened up during the past quarter of a century; and it is impossible to read them without realising that we are living in a golden age of scientific discovery. The talents with which scientific workers have been entrusted have been used to full purpose; and the results obtained are worthy of both royal and national pride.

In the main part the results represent scientific researches undertaken purely with the view of revealing natural phenomena and discovering new relationships or interpretations of them This urge to penetrate into the unknown and reveal its mysteries cannot be repressed any more than can creative expression in art or literature When, however, the spirit of an age is sympathetic towards any such intellectual activities, their advancement is increasingly ensured On this account, acknowledgment must be made of the part played by the Department of Scientific and Industrial Research in the increase and use of natural knowledge The Department was formed during the War as the result of a memorial from the Royal Society and other scientific and technical societies, exactly twenty years ago, urging the Government to afford assistance "for scientific research for industrial purposes" Two years later, Parliament placed a sum of one million pounds sterling at the disposal of the Committee of Council for the promotion of industrial research, and since then the Department instituted by the Committee has devoted a large part of the funds it derives from the State to fundamental scientific research in universities and other institutions, as well as in the promotion of research directly applied to industry Two other national research organisations which have come into being during the past twenty-five years are the Medical Research Council and the Agricultural Research Council The former arose from the Medical Research Committee, which was appointed for the purpose of dealing with the money available for research under the National Health Insurance Act of 1911, and provision for organised research in agriculture may be said to have grown up from the Development Act of 1909

In addition to these and other endowments of research provided by the State since King George's accession to the Throne, there have been several munificent benefactions from private sources to establish research institutions or explore specific fields of investigation. On account of these extended facilities, the number of students and others engaged in scientific or industrial research has been multiplied many times during the past quarter of a century; and the output of original papers has increased to such an extent as to be unwieldy, and even oppressive, to scientific workers who desire to keep in touch with advances in their subjects Our own correspondence columns represent this stream of tendency on a small scale,

yet they are but a rivulet of the broad and swift river which is bearing rich cargoes of new knowledge to peoples along its banks and to ports in the seas beyond.

To attempt to survey adequately the scope and substance of scientific publications of even a single week would be to undertake a hopeless task It is easy to understand, therefore, how incomplete any record must be which has to take a retrospective view of scientific progress in a period of twenty-five years Obviously the only practicable plan is to select for description subjects which have opened new epochs of scientific history during the reign of the King, and not to endeavour to summarise developments in various branches of the physical or biological sciences Beginning, for example, with the stellar universe, the knowledge gained during this period has led to entirely new conceptions as to its dimensions and structure, and their relation to the principle of relativity Coming down to the earth, the views now generally accepted as to its age and constitution differ substantially from those formerly held, and are based upon firmer foundations. From the planet earth it is a natural transition to the planetary microcosm of the atom Closely related are such subjects as isotopes, induced radioactivity, crystal structure, cosmic rays, the attainment of low temperatures, the constitution of the upper air, and weather forecasting As to man himself, new light has been thrown on his ancestry and the factors favourable to his healthy development or injurious to it, as well as on the problems of heredity involved in his future Chemistry is largely concerned with these and other biological problems, and has been able to give new aspects to them In applied science the discovery of special steels has been largely responsible for progress in many directions, and without them there could not have been the remarkable developments in X-ray apparatus, radio communication through the use of thermionic valves, aeronautics or turbine machinery These are the considerations which have decided the general order of the thirty articles now published.

The advances of knowledge have been accompanied by noteworthy changes of attitude of science towards philosophic and social problems. The implications of the theories of relativity and quanta, particularly in relation to notions of space and time, brought the physicist and mathematician into the realm of philosophy, while the philosopher has been giving attention to fruitful work in such specific problems as the nature of sense-data and their relation to physical entities, the character of space and time in their relation to one another, the basis of scientific induction, the interpretation of life and other intellectual concepts Modern physical interpretations of the nature of the universe have thus led to the discussion and development of associated metaphysical problems, and the two fields of thought are now regarded as complementary to one another

The view that the sole function of science is the discovery and study of fact, without regard to the philosophic or ethical implications of the knowledge gained, has undergone great modification in many minds It is realised that science cannot be divorced from ethics or rightly absolve itself from the human responsibilities in the application of its discoveries to destructive purposes in war or economic disturbances in times of peace Men of science can no longer stand aside from the social and political questions involved in the structure which has been built up from the materials provided by them, and which their discoveries may be used to destroy. It is their duty to assist in the establishment of a rational and harmonious social order out of the welter of human conflict into which the world has been thrown through the release of uncontrolled sources of industrial production and of lethal weapons.

It would scarcely be appropriate to deal with these aspects of scientific progress in the present collection of articles, though they are likely to become of increasing importance in national polity and international adjustments We believe, however, that the wide range and high authority of the contributions now brought together in celebration of the silver jubilee of the King's reign are worthy of the occasion It would be easy, of course, to point to other subjects which might have been included appropriately in such a retrospective survey, but, on the other hand, it would have been most regrettable to omit a single one of the present contributions, and these by themselves would make a volume of reasonable size if published in that form instead of the pages of NATURE. The articles are offered as a tribute of loyalty from scientific workers to the King and Queen; and it is hoped that they will be regarded as a stimulating conspectus of advances in natural knowledge during a memorable twenty-five years

Twenty-five Years in History

By F S MARVIN

KING GEORGE'S reign will always be remembered in history for three, or rather four, unique events of world-wide as well as national importance It has contained the whole period of the greatest war in history and the more difficult part of the reconstruction which followed it It has seen the foundation of the League of Nations and its early growth It has witnessed an unparalleled economic depression from which we are now slowly recovering, and which we hope and believe His Majesty will survive to see completely overcome Lastly, in the sphere with which NATURE is more specially concerned, the King's reign covers the establishment of the most far-reaching transformation of our ideas of the material universe, for Einstein's ideas gained general acceptance just after the conclusion of the War

It is one of the ironies of history that the greatest of wars should thus be connected with the name of one of the most pacific of kings But there was not for a moment any doubt that the King fully sympathised with his people in all the four years of their trial, in spite of the family ties which connected him with the most formidable of their opponents After the War, one noticed a marked increase in the public affection and esteem for a man whose good qualities at first suffered somewhat from a comparison with the *bonhomie* and genial character of his father, and when, at the end of 1928, he was for a time laid low by a serious illness, it was clear that he had already won all hearts Time has only strengthened that position. He is so obviously the good and devoted man, ready to bear everything and do everything for the sake of others, and, above all, for the restoration of the country and its prosperity in peace.

Next to the War, the League of Nations is, of course, the largest political issue of the King's reign. In this matter the King was fortunate in his position, and better guided by political instinct than the contemporary head of the American Republic. He was able, quite impartially, to commend the League as a common interest to all his subjects, whereas it unfortunately became a party issue in the United States. In England, King George could ask all his subjects to give it their support, and, with the aid of Great Britain and the British Dominions, it has already attained considerable success. France too has been a loyal supporter; but, in the British Commonwealth, there was a league within the League without which the effectual functioning of the larger organisation is scarcely thinkable At the moment, the adhesion of Russia and the close co-operation of the United States do much to set off the temporary abstention of Germany and Japan The current year, which ushers in the King's jubilee, has seen several instances of the value of the League's work in carrying out the pacification of the world on lines entirely in accordance with the King's life-desire

The work of social reconstruction, of healing the wounds of war and making provision for a fuller life in future, is still upon us It was seriously aggravated, at about the time of the King's illness, by the bursting on the world of an economic depression which was as unparalleled in its severity as the War It does not fall within the scope of this article to discuss the causes of this or the remedies which are now slowly overcoming it Some of the difficulties no doubt are due to the fact that the resources of science in multiplying the productivity of the earth have for the time outstript our methods of distribution, and national barriers and new notions of national self-sufficiency have hindered the free circulation of the products But one thing relating to science and arising directly from the War falls to be noticed here The War stimulated scientific experiment on the mechanical, physical and chemical sides as it had never before been stimulated in history. The evil necessities of the time forced on work in the laboratory, in the forge and in the air which have had many not-evil results Civil aviation has largely profited from what our engineers devised and our pilots carried out mainly over the Western Front So also in the chemical laboratories, aiming for the time at the destruction of other men, an activity was developed which has since taken other directions The Department of Scientific and Industrial Research, which now conducts inquiries into many matters of permanent national concern, dates from this time It now has its own research stations and promotes the work of twenty-two industrial research associations One may quite truly —while earnestly desiring a further abatement in the manufacture of arms—consider that most of the swords forged for slaughter have since been turned into ploughshares and pruning hooks

So strange is the balance of good and evil in life that, while we were all, quite rightly, deploring the extinction of so many young and promising lights of science in the great catastrophe, science itself was taking some of its most prodigious strides forward

It will always be remembered in history that the same year which saw the Treaty of Versailles and the establishment of the League of Nations, saw also the confirmation of Einstein's theory of relativity in the eclipse of the sun in 1919. The greatest step towards the permanent peace of the world coincides with the greatest step towards the establishment of the most comprehensive physical conception of the universe. In that eclipse the apparent displacements outwards of the positions of stars in relation to the sun, as shown on photographs of the eclipse, were found to be consistent with Einstein's calculations and confirmatory of his special theory. From that time onward, what had been regarded rather as a private speculation of an eminent man, took rank as the leading conception of a new era of thought. It is now found at the root of all the physical speculations about the material universe which make the more recent part of King George's reign one of the most notable epochs in the history of science.

The new outlook comes home to us more closely at the time of national rejoicing, because so many English and Anglo-Saxon names stand on the record of the advance. Two—Jeans and Eddington—are household words. Within ten years of the confirmation of Einstein's theory, man seemed to have gained a closer insight into the physical constitution of the universe than all the previous centuries had offered. It was shown to be congruous with the nature of the atom as revealed in the laboratory. New lines of development were suggested by which the heavenly bodies had assumed their present form and light. A view was thus attained which looked into the future as well as the past, and knit together what had been thought of as an infinity of space, into the expanding mind of man. This new synthesis was intimately connected with Einstein's theories, and its application, in the interiors of the stars and the remotest recesses of space, was made possible by the extension of photographic and photometric methods. An alliance was set up between work in the laboratory and work with the telescope which has led to the latest discovery of a universal fundamental number, which Sir Arthur Eddington explains in his new book.

It was thought at first that the new views were a revolution, and that Newton was superseded. But Einstein himself never countenanced this conclusion. To him, Newton was merely corrected and supplemented, and new and old thought found their place together in one essentially continuous evolution. But no doubt a shock was given to the finality of Victorian science in more than one respect. The universe of matter was no longer a finite thing, enclosed within an infinity of empty space. It became an expanding finite, full and similar throughout. Moreover, whereas absolute certainty and precision seemed to be given by the old Newtonian synthesis, the new view, coloured by the quantum of Planck, introduced an apparent indeterminacy into the old and apparently rigid laws.

In another respect the progress of science in the new century does not follow precisely the programme anticipated in the nineteenth. Thinking then that the Newtonian synthesis was final, it was commonly expected that the twentieth century would see added to this accomplished fact, another, equally complete and final set of laws, co-ordinating the phenomena of life. Now, in spite of the enormous extension of biology, this attractive prospect has certainly not been realised. Mathematical thinking has gone on pervading wider and wider fields, and gaining the conspicuous triumph which Sir James Jeans has made familiar to all. But biology, though invaded by mathematics and though engaging a constantly larger army of workers, has reached no synthesis comparable to that of Newton for astronomical physics. It has become more and more dispersed and specialised. The Mendelian laws have been added to Darwin's, but the nature of heredity and the cause of variations remain still in the realm of eager inquiry and speculation rather than of ascertained truth. The immediate sequel both of Darwin and of Mendel was rather the setting men to think and examine the details more closely, than the drawing of conclusions from well-established principles. Not deduction, but increasing experiment and induction, are still the leading features.

During the War, a school of biologists began to be spoken of as 'neovitalists', of whom the best-known name is that of Driesch. They were opposed to the idea that, by pressing on the investigation of the physical and chemical conditions of life, we might ultimately grasp the origin and nature of life itself. Such work is, of course, being incessantly done, and is one of the most prominent features of the biology of the day. But the school of neo-vitalists maintains that life is a thing *sui generis* and that, however far we may explain its conditions, we can never explain *it*, any more than we can explain the fact of consciousness by analysing the components of our sensations. Bergson, the most famous philosopher of the period, gave powerful support to this school of thought by developing his conception of an *élan vital* on the psychological side. On the biological, it revived to some extent the idea of Lamarck that the living being stretched out in the direction of its advantage in life, and that the result of such efforts were transmitted by inheritance from one generation to another. Such transmission is at the moment

denied by the majority of biologists, but a vigorous school of thinkers, finding their inspiration rather in philosophy than chemistry, are working to reconcile progressive work in biochemistry with the study of life in the concrete There are indeed signs that the rest of the century may come to justify the glowing prediction of the late Prof Patrick Geddes, that it would see the triumph of life and be the age of biology It is already true, in the more general sense, that men accept as a philosophical idea the community of all life and the development of higher forms of life from lower by some process in time which we have still to unravel

It would be well if one could speak of the acceptance of a community of human life on the planet with as much confidence as the growing consensus of opinion as to its origin In this matter, while the King's reign is distinguished by the establishment of the League of Nations, it cannot be said that the idea which it embodies or the practices which it exists to promote have made commensurate progress with what we have had to record of the progress of science. In some respects, there has been in recent years an actual setback Germany and Japan have renounced the League, and the United States, though helpful and friendly, has not formally joined even the Court of International Justice at The Hague Armaments have lately increased and no effective grouping or control of aviation has yet been effected There could be no more flagrant instance of the contrast between the unity of thought, which has given man his command of Nature, and the want of unity in his application of it, than this wanton rivalry in military aviation The most highly scientific means of transport and intercourse still threaten us as the most terrible method of mutual extermination, and the nations refuse an obvious resource to common action, common command, or even a common time-table for pacific purposes Nothing could better signalise the later years of His Majesty's reign, or be more in keeping with the master-spirit of the man whose life we prize and are now commemorating, than the conclusion of such an agreement It would be backed by all the scientific opinion of the world, and be the most striking proof of the progress of the reign in its essential quality—the pursuit of peace

The Structure of the Universe

By SIR JAMES JEANS, F R S

IN the last quarter of a century, our picture of the astronomical universe has changed almost beyond recognition, and yet we seem to be standing only on the seashore of the great ocean of knowledge

The geocentric view of the structure of the universe became untenable for thinking men in the year 1610, but in 1910 many astronomers favoured a 'galacto-centric' view, believing that the galactic system was the central and dominating feature of the astronomical universe, with the earth very near to its geometrical centre

Sir William Herschel had shown that such stars as he could see in his telescope constituted a coin-shaped structure, the more distant stars combining to form the faint band of light we call the Milky Way. In the astronomical language of 1910, a few classes of objects—spiral nebulæ and globular star-clusters—were found to 'shun' this plane, but the majority—irregular and planetary nebulæ, blue and Wolf-Rayet stars, eclipsing and Cepheid variables—'favoured' it, ranging themselves about this plane like flies on the two sides of a fly-paper For this reason the plane of the Milky Way was thought to be fundamental in the structure of the universe.

So far back as 1755, Kant had shown that other views were possible, suggesting that the elliptical nebulæ were not "enormous single stars, but systems of many stars" similar to our own, but at so vast a distance that their light "on account of their immense multitude, reaches us in a uniform pale glimmer"

Herschel adopted this view, speaking of these supposed other systems of stars as "island universes". It fell into disfavour for a time, but Eddington, writing in 1914, remarked that "the hypothesis has recently been revived as regards the spiral nebulæ" He continued "It must be admitted that direct evidence is entirely lacking as to whether these bodies are within or without the stellar system".

Then Hubble found it possible to measure the sizes and distances of these objects, and the problem was solved. Certain standard objects are believed to shine with the same intrinsic luminosity wherever they occur in space, so that their apparent faintness at once gives a measure of their distance Among such standard beacon-lights are Cepheid variables of assigned period, long-period variables, blue stars of assigned spectral type, and novæ at maximum. Examples of most of these standard

objects can be detected in the nearer nebulæ, and happily all tell substantially the same story as to the distances of these nebulæ They tell us that the nearest nebula of all (M 33 in Triangulum) is about 800,000 light-years distant, while the second nearest (M 31, the Great Nebula in Andromeda) is at a distance perhaps about three per cent greater This latter nebula subtends an angle of about five degrees in the sky, so that its diameter must be about 70,000 light-years The diameter of our galactic system is generally supposed to be at least three times this.

Such measurements and studies have made it clear that these nebulæ are systems of stars like our own galaxy, that they lie entirely clear of this and are substantially smaller than it is If we represent our own galaxy by London, then Birmingham and Bristol will represent the two nearest external galaxies fairly well in respect of both size and distance A small nebula (M 32) which accompanies the Great Nebula in Andromeda may be represented by Wolverhampton or Coventry Also two minor star-systems, the Magellanic Clouds, which lie so near our own galaxy (90,000 light-years from the sun) as almost to form part of it, may perhaps be compared to Croydon and Sutton We must not place our sun in Central London, as Herschel imagined; rather we are out at Hampstead or Highgate, and see the lights of Central London and the smoky pall over it in the distance, when we look towards the great star-clouds and dark nebulæ of Sagittarius.

Most of these nebulæ show the same flattened shape as our own galaxy, and it has long been conjectured that this flattening must indicate rotation Recently rotation has been discovered spectroscopically in a number of the nebulæ The central part of the Great Nebula in Andromeda, for example, rotates with a period of about 16 million years, while that of the well-known nebula N G C 4594 in Virgo rotates about twice as fast Quite recently Oort, Plaskett, Lindblad and others have found that the galactic system is also in rotation The stars revolve much like the planets or the particles of Saturn's rings, the period of revolution increasing as we pass outwards At the sun's distance it is at least 200 million years. This is 12½ times the period of revolution just mentioned for the Andromeda nebula, but it refers to a point six times as far out If the whole of this latter nebula were concentrated in or near its centre, the rotation period at the sun's distance out would be about 235 million years, so that the rotations are at least comparable.

From these rotation periods, it is of course possible to calculate the masses of the nebulæ and of the galactic system. The nebulæ are found to have the masses of thousands of millions of suns, while the galaxy has a mass of 100,000 million suns at least We see that our galaxy is something of a giant in mass as well as in size, if the nebulæ are island-universes, we still inhabit a continent.

As we proceed outwards into space, the Cepheid variables and other standard beacon-lights so far mentioned sink one after another into invisibility. Hubble has, however, found that nebulæ of assigned shapes and structure are themselves standard articles to a reasonably good approximation Thus the faintness of the nebulæ themselves gives a measure of their distance, and it becomes possible to estimate the distances of even the faintest nebulæ, right up to the limits of vision of the telescope The nebulæ prove to be distributed fairly uniformly at an average distance apart of perhaps 1,800,000 light-years.

If the matter contained in all these nebulæ were scattered evenly through space, the density would be of the order of 10^{-30} grams per c.c This may give a clue to the mode of formation of the nebulæ, since a gas of this density would tend to condense into 'droplets' of just about the observed masses of the nebulæ If nebulæ originated as such condensations in a fairly uniform gas, we have a ready explanation of the comparative uniformity of their sizes and structure.

When the light from any one of these distant nebulæ is analysed spectroscopically, the whole spectrum is found to be displaced homologously towards the red end If we interpret these spectral displacements in the simplest way, as pure Doppler-effects, then these nebulæ are found to be receding from our galaxy at speeds almost exactly proportional to their distances—roughly, 105 miles a second for each million light-years of distance—and when allowance is made for the sun's motion through the galaxy, the same is found to be true of the nearer nebulæ also In brief, the whole universe appears to be expanding uniformly, its linear dimensions increasing by one per cent every 20 million years.

It is likely that this apparent recession of the nebulæ is something more than a mere astronomical phenomenon, for the generalised theory of relativity seems to call for an expansion (or alternatively a contraction) of space itself. Thus the motions of the nebulæ may well be indications of something far more fundamental—a uniform expansion of the space in which they are imbedded.

The theory of relativity associates gravitation with a curvature of the space-time continuum; this is curled up in the proximity of matter, and the curvature shows itself in the curved paths of planets and projectiles. At one time it scarcely seemed possible that the whole curvature of the space-time continuum could be of this kind, for analysis showed that, if it were, space could

not stand still; it would either expand or contract. To avoid this apparent absurdity, Einstein imagined the continuum endowed with a further curvature of its own, independent of the presence of matter and so inherent in the space itself This was specified by a quantity, the 'cosmical constant', which was supposed to have a uniform value everywhere and so kept the total volume of space fixed and unalterable

There is no observational evidence that such a constant exists, for the curvature it implies is too small for measurement The constant was only introduced because Einstein had thought space must be at rest, and there is no need to retain it now that space appears not to be at rest On the other hand, we are under no compulsion to discard it. Actually Einstein and de Sitter have found that the constant can have a large range of values, including zero, without running counter to any of the observed facts of astronomy

We may compare space-time to a river having space as its cross-section and time as the direction of flow of its stream Two dimensions are, of course, missing, the cross-section of our river ought to have three dimensions instead of one, but as all three are all exactly similar, the suppression of two of them does no great harm

If space could remain constant in size, this river would become a canal with parallel banks, Einstein's original space-time river was of this type But Friedmann and Lemaître showed that such a space would be unstable, any slight disturbance or irregularity—such as would, for instance, be caused by the condensation of a primeval gas into nebulæ—would start it either expanding or contracting For this reason Lemaître thought that the Einstein canal should be replaced by a sort of Amazon River, starting from minute beginnings and for ever widening as it flows—expanding space De Sitter found that other values for the cosmical constant made two other types of solution mathematically possible In one of these the canal-like river gives place to a sort of Panama Canal—space first contracts until it reaches a minimum and then expands again to an indefinite extent In the other, space rhythmically expands and contracts, so that the space-time river becomes a series of regularly spaced lakes connected by narrows

The Amazon-like space-time river of Lemaître was open to one grave objection Its length, which is time—the whole time since the beginning of the universe—was limited, and its source was nothing like distant enough to allow for the observed stages of development of stellar systems —in brief, the stars were too old to have grown up within the length of the river

The two more recent solutions of de Sitter and Einstein are not open to any such objection, and at present either of them appears capable of providing a true, although highly artificial, representation of the observed phenomena of the universe At one time, de Sitter was advocating the Panama canal type of map, while Einstein favoured the rhythmical universe of lake and narrows—a space which alternately expanded and contracted Einstein now appears to contemplate the possibility of a zero cosmical constant and a space of infinite extent But it is, I think, fair to say that no one is satisfied with the present position It may be that still other alternatives remain to be discovered, and another few years may witness some new formulation of the problem which will lead to a satisfactory solution.

The New Age in Physics

By DR. H. DINGLE, Imperial College of Science and Technology, London

EVERY advance in thought has two aspects —the loss of the old and the gain of the new—and it is probably inevitable that, after the first flush of excitement has faded away, the former should become the more conspicuous It may inspire joy at the passing of a delusion, or regret at the failure of an ideal: in either case it is the negative aspect of the change which protrudes itself, because all are conscious that what they believed in has gone, but only a few can at first see the significance of the new thing which has come.

This is exemplified by the fact, which is in all our minds to-day, that King George V has occupied the throne of England for twenty-five years. What does it mean? In 1910 we knew well enough what it would mean, but in 1935, who except a mathematical physicist will commit himself to an opinion? Twenty-five years to one observer, we are told, may be fifty years to another, and neither can claim superiority for his time-scale Why, then, not celebrate a golden instead of a silver jubilee? The relativist knows, of course, that the destruction of absolute time is merely the necessary preliminary to the building of an absolute 'interval', and that twenty-five years is the *interval* during which King George has reigned In this matter His Majesty's time is *proper* time, so that physics

and patriotism support one another. But for one to whom this is the significant aspect of relativity, there are a thousand who know only that where they thought was certainty there is only confusion

It will not be amiss, therefore, to look at the positive side of the changes in physical thought which the past twenty-five years have seen. What principles have been introduced into science during that time, or having already existed there, have been more clearly understood and more rigidly applied? How does this epoch appear against the broad background of scientific history? What is the character of the tide as distinct from the wanderings of individual waves? Only future historians can give final answers to these questions, but we may attempt to answer them in a manner fitted to the needs of our time

There seems little doubt that the essential contribution of relativity to science is the principle usually known as 'the rejection of unobservables'. It is not new in the sense that it has never before been applied: on the contrary, it is exemplified in almost every forward movement which physics has made But it has been used unconsciously, instinctively, and therefore to some extent inconsistently. It has now been brought into the light of day. That is the significant thing, beside which the consequences to our understanding of mechanics and gravitation are of secondary importance

It is very doubtful if this principle has yet been properly formulated, and quite certain that its full implications have not yet been grasped. It is probable, too, that it has on occasion been wrongly used. Though in appearance a merely negative principle, it is in fact a positive instrument of incalculable power We venture to suggest the following two statements as a provisional expression of its meaning:

(1) *The criterion of objective physical existence is general observability by physical means**.

(2) *In the logical correlation of experience, the concepts employed shall be such that whatever is not generally observable by physical means is necessarily meaningless*

Particular attention should be directed to the word 'necessarily'. It is not enough to reject unobservables: we must frame our laws of Nature so that they cannot arise to be rejected It is this that makes the principle an inherently positive one. Its first fully conscious application by Einstein illustrates this excellently. It is not sufficient merely to say that because it is impossible to observe motion relative to the ether, such motion is meaningless. We must define the concepts of space and time so that its meaninglessness is a necessary consequence. This Einstein did, and therein lies his greatness

So fundamental is this principle that some of its requirements are at present far beyond the possibility of practical application: they belong to the future Consider the age-old question: Does an object exist when no one is observing it? The first part of our principle immediately answers, No: for clearly it is impossible to observe an object at a moment when no one is observing it. Consequently, our final physical terms must be such that the question has no meaning

Now the whole of what is known as 'field physics' necessarily involves existence without observation. Our observations are scattered, atomic, discontinuous, and we assume a continuum or continua (space, time, ether) in which they are distributed. Our field laws consequently describe realms of possibility rather than bits of actuality The law of gravitation does not tell us the structure of the solar system It gives us a prescription according to which an infinitude of solar systems might be built, but it cannot by its very nature tell us why we have our particular one Our principle requires that this form of theory must be discarded

Needless to say, the value of field theory as a means of advance is far from exhausted: it is its status as a possibly final form of scientific expression that is destroyed. Nor should this surprise us. A complete theory of the universe—that is, of all that is physically observable—can scarcely be pictured as a set of super-universal laws supplemented by an independent statement of how, from some quite arbitrary starting-point, a particular system developed in accordance therewith We should not be satisfied with any theory of the universe which did not give the details of the system equal inevitability with the laws according to which those details took shape We can, indeed, deduce this directly from our principle The universe cannot be regarded as one of a number of possible universes, because the others, being unobservable (our own comprises all that is observable), cannot exist Hence our final account of it cannot be in terms of field theory.

From this point of view it is highly significant that during this same period of twenty-five years the other great branch of modern physics—quantum theory—has been transformed from the heretical speculation of a few daring theorists into a system with claims to universal scope. Quantum theory, unlike field theory, postulates no unrealised possibilities; it opposes discontinuity to continuity, and seeks to describe the actual rather than the possible. It provides the very soil in which the

* That is, intrinsic observability: for example, an object is not to be considered unobservable merely because one is not in a position to observe it.

principle of rejection of unobservables would be expected best to flourish

The principle does flourish there, but again the result is generally seen more as a negative than as a positive achievement we are far less conscious of the growing fruit than of the lost blossom The supreme product of the quantum theory so far is described as a 'principle of uncertainty', and it is often regarded as having ousted causality from Nature It is worth while looking at this matter for a moment in its historical setting.

The idea of causality in its elementary form is almost as old as thought itself · intelligent action is impossible without an assurance that a given act will be followed by an expected event Only at a later stage of reflection is volition eliminated, so that the initial and final states of the physical system concerned are seen standing in causal connexion ; and it is still later that the conception is extended throughout space, the state of the universe at one instant being regarded as the effect of its immediately preceding and the cause of its immediately succeeding state This was the level of thought when Newton's laws of mechanics apparently placed the reality of the conception beyond question by discovering the clue to the inevitable succession of states Newton gave formulæ by which, if the position and momentum of each particle of matter in the universe at any one instant were known, its position and momentum at the next instant could be determined, and hence its position and momentum throughout all time, supposing it to be eternal.

Newton's mechanics has been modified in various ways, and the study of radiation, electricity and such phenomena has revealed a richer physical universe than that which he contemplated, but none of these developments has destroyed the possibility of prescribing the data necessary to predict the future course of events The fundamental modification of Newton's contribution to the idea of causality has come from the study of the means by which data are obtained Minute investigation shows that it is impossible to determine exactly the simultaneous position and momentum of any particle of matter because our means of observation are such that precision in one determination can be obtained only at the expense of precision in the other

It is important to see just what this means. In one sense it virtually puts us back to our position before Newton. We cannot state what are the data which would enable us to predict the future of the universe, but we may, as then, regard the predictability of its future as a generalisation of our experience of causality in limited systems of events. How far such generalisation is legitimate is indeed an important question, but it is not affected by recent work Galileo could have discussed it with us without being at much disadvantage. Furthermore, the experience of causality in limited systems is a fundamental fact. It is impossible that scientific developments can overthrow it without destroying their legitimacy, for it is their basis The sum and substance of the matter is that we have found that the data by which we thought we could forecast the future are unattainable

There is an important difference between this and the statement which is frequently made, that the quantum theory requires that an experiment can be repeated several times under precisely similar conditions with various results. If that were true, it would indicate an irrationality in Nature which would be the negation of science. What the theory does show is that, if we define similarity of conditions as similarity of positions and momenta of the physical systems concerned, we can never be sure that we *are* repeating the experiment under precisely similar conditions The distinction is profoundly important, for the actual situation leaves open the possibility that other data may be specified which will precisely identify a system, whereas the incorrect statement leaves no room for such a possibility

Now it is just at this point that our fundamental principle of rejection of unobservables comes in Since simultaneous position and momentum are unobservable, we must not only reject them, but we must also re-express our laws in terms according to which they have no meaning Position and momentum are functions of the continua, time and space, which are appropriate to field theory, but cannot be expected precisely to fit phenomena which are essentially discontinuous The problem of physics, then, is to devise other terms

That such terms are possible there seems little reason to doubt A useful beginning has been made with the concept of probability. This is expressed mathematically as a ratio of integers, and so is more appropriate to discrete phenomena than any kind of continuous extension It is sometimes said that we can no longer use models to represent physical conceptions. This, of course, is inaccurate, or physics would have no place left for the man with imagination ; it would be a sphere of action only for the robot What has happened is that mechanical models, which are spatial, have given way to epistemological ones, which are integral To regard this as anything but a step towards better conceptions is to miss the significance of the new enlightenment The error of the nineteenth century physicists was not that they used mechanical models (which were

entirely appropriate to their stage of development), but that they did not recognise them as models To imagine that probability has any greater claim to inherent permanency than mechanisms—and, in particular, to draw fundamental conclusions from the accident that probability suggests an intrinsic uncertainty—is to make the same error

It seems likely that the quantum theory, so far from expelling precision from our description of Nature, really opens the door to it for the first time For strictly speaking, a field theory can never allow absolute precision since continua are infinitely divisible A particle having a co-ordinate represented by a non-terminating decimal, for example, could have its position specified as nearly exactly as we pleased, but not with absolute exactness, and an infinite future would hold the possibility of an indefinite amount of departure from a prediction based on such specification. Data which must necessarily be expressed in integers, however, are clearly susceptible of absolutely exact expression The present position is therefore that we have escaped from a scheme of thought which made precise prediction impossible into one which, though we are as yet less far advanced in it, offers absolute precision as a possible goal

Comparisons, if not odious, are liable to be misleading, and it would be unwise to stress them Nevertheless, it may well be doubted whether in any previous period of twenty-five years, physics has experienced a more substantial forward movement

Constitution of the Earth

By Dr. Harold Jeffreys, F.R.S., St John's College, Cambridge

COMPARING the position of geophysics now with what existed in 1910, while we are struck by the great development that has taken place, we are equally struck, on looking more closely, by the fact that most of the theoretical advances are due, not to specifically new methods, but to the fuller application of methods that were already known The work of Kelvin and Sir George Darwin on the rigidity of the earth, and on the evolution of the earth-moon system under the action of tidal friction, was already classical, Darwin's theory of the stresses needed to support continents and mountains was thirty years old; the existence of isostatic compensation, and the two alternative explanations of Pratt and Airy, had been known for fifty years, Stokes's theory of the determination of the figure of the earth from observations of gravity for sixty, and Poisson's theory of the longitudinal and transverse waves in an elastic solid for eighty Dr C Davison, still with us, had put the thermal contraction theory of mountain formation on a quantitative basis in 1887, and Wiechert had shown how to reconcile the earth's ellipticity and precessional constant on the assumption of a thick rocky shell surrounding a dense metallic core The existence of a change in properties in the crust in the continents at some small depth had already been inferred from geological considerations by Suess

The chief new advance in the first ten years of the present century probably arose from the detection of radioactivity, the recognition of its effect in modifying the earth's thermal history, and the use of the rate of disintegration of uranium to find the absolute ages of minerals and to calibrate the geological time-scale The age of the earth, estimated from thermal considerations by Kelvin at about 20 million years, was suddenly raised to about 1,500 million Physicists did not all accept the new estimate without a struggle, though purely mechanical considerations might have given some ground for doubting Kelvin's value Darwin, by adopting such a viscosity in the earth as would make the changes through tidal friction occur at every time at the maximum rate, the viscosity thus varying with time in a way very unlikely to correspond to the facts, could not bring the age of the moon below 54 million years This might have been taken as an absolute minimum that was practically certain to be greatly exceeded.

The new source of heat was so potent that the present Lord Rayleigh pointed out that, if it was not confined to a depth of some tens of kilometres at the outside, it would produce more heat than is escaping from the earth; consequently it led Holmes to estimate the rate of decrease with depth It was found to suggest that average granite could exist only to a depth of about 15 km. and agreed in principle with the conclusions of Suess.

Meanwhile, seismology made three great advances. Herglotz and Bateman provided a method of finding the velocity of an elastic wave at any depth in the earth from the observed times of travel of earthquake waves, which was first applied by S. Mohorovičić in 1916. R. D. Oldham found that longitudinal waves arrived at the

opposite side of the earth about three minutes later than they would if the velocities found from observations at shorter distances were maintained to the centre, and inferred that at a depth of about half the radius there was a change of properties involving a diminution of velocity The radius found for the core in this way was substantially less than that found by Wiechert, but it was not until 1926 that it was noticed that the compression of each layer in the earth by the weight of the matter above it would raise the density so much that, when it was allowed for, the radii found by Wiechert's method and Oldham's were practically identical, so that the Wiechert core and the Oldham core are the same thing A Mohorovičić, working on a small earthquake in Croatia in 1909, found that the records at short distances could not be represented by a medium the properties of which varied continuously They showed a pair of strong longitudinal and transverse waves, which were overtaken at a distance between 100 km and 200 km. by a weaker pair that travelled faster, the latter corresponded to the waves observed at greater distances The interpretation is that the strong pair observed only up to distances of about 800 km travel in an upper layer, while the others travel with greater velocities through a lower region of great depth The correspondence with the geological and thermal considerations is plain.

All these lines of investigation were greatly developed by Gutenberg, particularly in relation to the waves through the core and reflected by it The reduction of the velocity of a longitudinal wave on entering the core is about that of light on entering water from air; consequently the core casts a shadow, which can be recognised by the absence of the clear direct waves beyond a distance of about 105° and their replacement by a vague diffracted movement, and the rays passing through it have a caustic surface, which meets the outer surface before it has come to a focus. Thus there is a narrow zone, at a distance of about 143°, where the motion in the longitudinal wave is extremely strong The estimated velocities led Gutenberg to calculate times of transmission of many other core waves, notably those reflected at its outside, the wave that is transverse in the shell but is partly refracted as a longitudinal one in the core, and one derived from the latter by undergoing one reflexion on the inside of the core before it comes out. These were all recognised on actual seismograms. It was much later, however, that attention was directed to this work in Great Britain, and Prof. H. H. Turner rediscovered several of Gutenberg's waves independently from the observational material supplied to the International Seismological Summary.

The most immediate consequence of the existence of the reflected waves is that the boundary of the core is a sharp discontinuity of material and not a gradual transition This gives a direct verification of the inference, based on a slightly dubious analogy with meteorites, that the shell is stony and the core mainly iron, with probably a certain amount of nickel Further, the mean densities found by combining the radius of the core with the mean density and the moment of inertia are about 4 5 and 12 respectively, but if we estimate what they would become if the high pressures were taken off, they are about 3 3 and 8, the former agreeing with the density of olivine and the latter with that of iron. The core appears to be liquid Gutenberg calculated what the times of transmission of transverse waves through it would be if it was solid, but though several workers have found movements that they have thought to be these waves, their results are not consistent and seem to be capable of other interpretations The most direct evidence on the state of the core is provided by the earth's tidal yielding, which is practically what it would be if the core was fluid, and substantially more than if the core was solid and had a rigidity in any reasonable ratio to its bulk-modulus

Further work on the records of near earthquakes has shown that there is at least one intermediate layer, and there may be three. The thickness of the upper layer is 12 km, with an uncertainty of 3–4 km, the intermediate ones together may be twice as thick The study of the surface waves, mainly by Stoneley, has given similar results with a rather higher precision The surface waves under the oceans, however, show a different structure, the thickness of the upper layer is substantially less, and the geological evidence indicates that it is not granite there, but probably andesite or even basalt

The chief modern contributions to seismological technique are probably the wireless time service and Bridgman's invention of a method of experimenting at high pressures Until recently, the time had to be determined independently by astronomical observation at every station, now a station with no astronomical equipment can fix its time with as great accuracy as was possible to the best in 1910 The result of this and of the increase in the number of stations is that the times of transmission of the various waves can be determined, in most cases, with an accuracy of a second or less, in fact, the accuracy is so high that it has become necessary to allow for the ellipticity of the earth before we can make full use of it, and it has only been attainable because the earthquakes used have been in much the same latitude, so that the effect of the ellipticity has always been nearly the same

Testing the compressibility of actual rock specimens at high pressures has shown that the velocities of elastic waves in the upper layer are consistent with its being granite, geologists seem to be coming to regard the upper layer as more like a granodiorite than a normal granite, but this is a minor change The lower layer fits olivine or dunite in elasticity as well as in density, it is definitely too dense and too stiff to be basalt, which, if it forms any extended layer at all, can only be the deepest and least clearly recognisable of the intermediate ones

A strong curvature near 20° of the curves representing times of transmission against distance was first noticed by Byerly, and work by I Lehmann, K E Bullen and myself has shown that there is a sharp change in the slope there This appears to correspond to an increase of the velocity by about 10 per cent at a depth of about 350 km The nature of this change is not yet understood Apart from the upper layers, this discontinuity, and the boundary of the core, there are no other sudden changes in properties with depth Search has been made for a sulphide layer, which has been expected to form the outermost part of the core, but it is necessary to do some violence to the observations to fit one in at all, and there seems to be no room for one more than a few kilometres thick at the most.

The study of gravity made a great advance in 1912 with the publication of Hayford's work in the United States, which showed that the larger mountain ranges of the United States are associated with such a defect of density below that the whole produces little disturbance of gravity Unfortunately this work, and the later work of Bowie, have suffered greatly from exaggeration and misinterpretation The general result was to assume that this compensation made a great reduction in the differences between observed and calculated gravity; but it did not abolish them. It was inferred by many that the approximate compensation was exact, and elaborate theories have been constructed upon it, assuming that it showed not only the lower layer, but even the upper ones, to be completely devoid of strength, in direct opposition to the plain fact that the surface of the earth is not perfectly flat Others, unwilling to accept the conclusion, have gone to the opposite extreme and denied that the observations imply any compensation at all It still does not seem to be generally recognised that a theory that reduces the average residual in a mountainous region from twenty times to six times the probable error of a single observation, is on a different footing both from a theory that reduces it to the mean error of a single observation and from one that does not reduce it at all On the other hand, the generality of the American results is not complete; they seem to apply to all the great mountain regions where they have been tested, but they break down in India and in the East Indies, as De Graaff Hunter and Vening Meinesz have shown

Meinesz's introduction of a method of determining gravity at sea by observing in a submarine is perhaps the greatest advance towards determining the figure of the earth accurately that has been made recently. Stokes showed how a complete knowledge of gravity over the earth's surface could give a determination of the external field, but so long as observations were available only over the land, and very limited proportions of that, we were in the position of trying to locate one end of a rod of unknown and variable curvature by observing a lot of points near the other. Now lines of observed values of gravity are available right across the main oceans, though there is still a great need for more in the southern hemisphere

The Measurement of Geological Time

By PROF. ARTHUR HOLMES, Professor of Geology, University of Durham

TWENTY-FIVE years ago, opinions as to the scale of geological time were still in a chaotic state. The earlier controversy between Kelvin and the geologists had come to a dramatic end in 1906 with the discovery by Strutt (the present Lord Rayleigh) of the widespread distribution of radioactive elements through the rocks of the earth's crust. The earth could no longer be regarded as a spendthrift living on a limited capital of ancestral heat. An independent source of income had been disclosed in the energy liberated during radioactive disintegration, and henceforth no thermal argument could set a limit to the age of the earth. Already, however, helium and lead had been recognised as the end-products of the uranium family, and Rutherford had suggested (1905 and 1906) that the accumulation of these elements in radioactive minerals might provide a measure of the age of such minerals.

In 1907 Boltwood made the first attempt to calculate the ages of minerals which had been analysed for uranium and lead. During the next three years, Strutt carried out his far-reaching researches on the accumulation of helium during geological time and on its rate of production in uranium and thorium minerals. Thus, by 1910

the foundations were being actively laid on which our present knowledge of the subject has been built. It was evident from the preliminary results that the earth might well be fifty times as old as Kelvin had thought Geological evidence, based on a statistical comparison of rates of denudation with accumulated sediments on one hand, and with the salinity of the sea on the other, had suggested a period of about 100 million years for the age of the earth The possibility that 1,000–2,000 million years might be available seemed to many geologists to be as embarrassing as the former limitation to 20–40 million years Interest in the validity of the rival methods was thus re-awakened, and most of the discussion of the last quarter of a century has rightly been focused on this fundamental aspect of the subject.

For reliable measurements of geological time we require to know (*a*) the rate at which some suitable process is going on at the present day, (*b*) the law of its variation during the interval to be measured, and (*c*) the cumulative change effected by the selected process during that interval

Except in their application to relatively short intervals, none of the geological methods fulfils these requirements Present rates of denudation are fairly well known over a wide range of environments, but there are many reasons for regarding their average as abnormally high compared with that of the geological past. River gradients are steeper than usual, because of recent mountain building, groundwater circulation is more active for the same reason, easily eroded blankets of glacial and fluvio-glacial sediments are widespread; and human activities—agricultural, engineering and chemical—have introduced a unique source of acceleration. Evidently no law of past variation can be formulated.

The total accumulation of sediments is difficult to estimate even approximately, since exposed sediments are worked over afresh by denudation, and deeply buried sediments may be metamorphosed beyond recognition by transfusion and granitisation Measures of maximum thicknesses provide comparable figures for the individual systems, but no corresponding rate of deposition is available, since the maximum thicknesses are really measures of crustal depression. If the sodium method of estimating the age of the oceans is apparently simpler in form and superior in quality, it is only delusively so, and not only because present rates of chemical denudation are high. The geochemistry of sodium is still insufficiently explored in two directions Sodium is probably returned to sediments by base exchange on the sea floor, and it is certainly added to them from plutonic sources by processes of albitisation and granitisation. The metamorphic cycle introduces incalculable sources of variation, but their effects are all in the same direction, so far as our problem is concerned All we can conclude is that the actual age of the oceans must be many times higher than the estimate calculated from present conditions

The radioactive methods are based on the generation of helium and of isotopes of lead from uranium, actino-uranium and thorium, and on the accumulation of these stable end-products in minerals, rocks and meteorites which have retained them The original uncertainties, which Becker and Joly never allowed to be overlooked, have now been completely dispelled Unless the contemporary state of scientific knowledge is as misleading in our day as it was in Kelvin's, we can now claim to be in possession of data that are securely founded in principle, and stable in the sense that continued research only increases their accuracy and extends their range*.

The present rates of production of helium and lead from uranium are well established ($U\,I \rightarrow Pb^{206} + 8He$). To a first approximation, the age of a uranium mineral is given by the ratio of lead to uranium, (Pb/U), ×7600 million years But the investigations of von Grosse on the actinium series, and those of Aston and of Piggot and Allison, in recognising and disentangling the isotopes of lead leave no room for doubt that the actinium series springs from an isotope of uranium, AcU, and terminates in Pb^{207} ($AcU \rightarrow Pb^{207} + 6He$) Thus, a slight error is introduced into the above formula, and this must be allowed for, especially in the case of old minerals At present, the ratio of AcU to U I is about 4 to 96, and the former disintegrates about ten times as fast as the latter Clearly the older the mineral the higher should be the ratio Pb^{207}/Pb^{206}, and hence this ratio itself constitutes an index of age

The chief defect in Boltwood's original use of lead-ratios only became apparent with the recognition that the thorium series also terminates in an isotope of lead ($Th \rightarrow Pb^{208} + 6He$). For a thorium mineral, the corresponding lead-ratio can be expressed as Pb/kTh, where k depends on the rate of lead production by thorium relative to that by uranium. Strutt's early work showed that k was not far from 1/3. Later estimates have varied between 0·38 (Lawson) and 0·25 (Kirsch) In Bulletin 80 of the National Research Council, Washington, D C., referred to above, the value

* A complete résumé of the subject up to 1931 appears in "The Age of the Earth", Bulletin 80 of the U S National Research Council, Washington, D C Since then a remarkable amount of new work has been accomplished, largely as a result of the direct influence and co-ordinating activity of the National Research Council Committee on the Measurement of Geological Time. The annual reports of the Committee, prepared by its energetic chairman, Prof A C. Lane, not only record the rapid progress which is being made, but also enable individual workers in various parts of the world to keep in close touch with each others' results and ideas.

0·36 was adopted by Kovarik and the writer, and more recent investigations by Kovarik, Ruark and Fesefeldt on the period of thorium have confirmed this value For minerals containing both uranium and thorium, as many of the suitable minerals do, the simple lead-ratio (uncorrected for the actinium complication and the wearing out of the parent elements) thus becomes Pb/(U + 0 36Th) The corresponding helium-ratio is He/(U + 0·27Th). If helium is stated in cubic centimetres per 100 grams of material, the age of the latter in millions of years (provided there has been no loss of helium) is given approximately by multiplying the ratio by 8·8

The question whether the rate of generation of lead isotopes and helium has varied during geological time has now been satisfactorily answered. None of the physical or chemical conditions appropriate to the terrestrial environment of radioactive minerals has been found to disturb in any way the normal rates of spontaneous disintegration. But this is not all Positive evidence of the inferred constancy of rate is provided by pleochroic haloes, the rings of which correspond in radii to the ranges of the respective α-particles responsible for their development The range of each α-particle is connected in turn with the rate of disintegration of its emitter by a simple law. Hence, if the ranges measured from pleochroic haloes in old Pre-Cambrian minerals are identical with those from Tertiary haloes and experimentally produced haloes, the chain of evidence is complete In 1923, Joly claimed that the uranium ring showed a progressive increase of radius with increasing age. However, more accurate measurements by Kerr-Lawson in 1927 failed to reveal the alleged increase, and indicated that Joly's identification of the rings had been at fault A recent study of haloes by Henderson, Bateson and Turnbull, in which a highly sensitive recording photometer was devised to measure the halo features, shows that there has been no variation of range, and therefore no change of rate of disintegration, over a period of a thousand million years. Henderson has also identified a ring due to actinium C and indicated how its development can be used in comparison with that of the radium C′ ring to yield estimates of age. Preliminary results are clearly of the right order.

The third condition of validity implies knowledge of the total accumulation of lead isotopes or helium in the radioactive material under investigation. To consider first the lead method: the presence of initial lead, if any, must be recognised and allowed for, and evidence is required that the mineral has remained uncontaminated by external influences since the time of its crystallisation Field occurrence, microscopic examination, chemical composition, atomic weight determinations of lead, and isotopic analysis of the lead all contribute data bearing on these important points After rejecting those numerous minerals which fail to satisfy the requirements, there still remain many for which the evidence of reliability is good. Assurance is confirmed when it is found (*a*) that minerals of the same geological age, but with varying values of U/Th, give concordant lead-ratios, and (*b*) that suites of minerals of varying geological age fall into an internally consistent time-scale A good example of (*a*) is given by uraninite and monazite from a Pre-Cambrian pegmatite in Manitoba Ellsworth obtained a lead-ratio of 0 260 from the first (a uranium mineral), while Miss Kroupa found 0 259 for the second (a thorium mineral), the corresponding ages being approximately 1,745 and 1,725 million years To illustrate (*b*) the data set forth in the accompanying table will suffice.

AGE DETERMINATIONS BY THE LEAD AND HELIUM METHODS

Geological Age	Material	Locality	Millions of years from	
			Lead-ratios	Helium-ratios
Miocene	Uraninite	Mexico	35	
	Brannerite	Idaho	38	
Tertiary	Tholeiite	Cleveland Dyke, Durham		28
Eocene	Basalt	Deccan, India		37
Late Cretaceous	Kimberlite	Transvaal		58
	Pitchblende	Colorado	60	
Late Jurassic	Ishikawaite	Japan	128	
Triassic	Dolerite	Connecticut		170
Early Permian	Pitchblende	Bavaria	205	
Close of Carboniferous	Dolerite	Whin Sill, Westmorland		196
Upper Devonian	Uraninite	Portland, Connecticut	283	
	Monazite		278	
Late Ordovician	Uraninite	Fitchburg, Mass	370	
	Cyrtolite	Bedford, N Y.	380	
	Uraninite	Connecticut	380	
Upper Cambrian	Kolm	Sweden	455	
Late Pre-Cambrian	Basalt	Gwalior, India		500
	Basalt	Keweenawan, Lake Superior		580
	Pitchblende	Katanga	600	

The early applications of the helium method led to the conclusion that only minimum age determinations were possible on account of the leakage of helium from radioactive materials. Such loss is inevitable when the internal pressure of generated helium becomes high. In recent years, however, certain feebly radioactive substances, such as native metals and iron meteorites, have been found to retain helium completely, and fine-grained basaltic rocks also seem to be satisfactorily retentive. The technique for the determination of minute quantities of helium has been developed by Paneth to such a degree of precision that the amounts accumulated in iron meteorites and in basaltic

rocks can now be accurately measured In 1929 the writer pointed out that "since igneous rocks suitable for the helium method are far more abundant and far better distributed in time than are radioactive minerals suitable for the lead method, there is now available a practical means of effecting long-distance correlations and of building up a geological time scale which, checked by a few reliable lead-ratios here and there, should become far more detailed than could ever be realised by means of the lead method alone" In the accompanying table some of the results which have since been obtained by Paneth, Dubey and Urry are listed

The oldest minerals so far reliably dated by the lead method are those of Manitoba, to which reference has already been made A similar age of more than 1,700 million years has recently been found for zircons from a South Dakota granite, which itself is older than the South Dakota uraninite analysed by Davis (1,465 million years) At least one cycle of sedimentation preceded the intrusion of these oldest known granites of North America, and by analogy with other such cycles, this would seem to indicate that the age of the earth cannot be less than 1,900 million years No approach to a closer estimate is practicable at present It is not improbable that a maximum limit may be set by the age determinations of meteorites made by Paneth and his colleagues The results range up to 2,800 million years, but while the origin of meteorites remains in doubt the significance of these figures remains speculative It appears possible, however, that the earth, the solar system and the present organisation of the stellar universe may all be of the same order of age, namely, 2,000–3,000 million years

To geologists, the exact age of the earth is of less importance than the application of age measurements to dating igneous rocks, correlating Pre-Cambrian formations in various parts of the world, and building up a reliable time-scale With the aid of the latter it is becoming possible to estimate the rates at which various geological processes have operated in the past It is already clear that, at least during the later part of geological time, there has been a remarkable acceleration of activity, and that during the Tertiary period, in particular, the earth was more vigorous in its behaviour than at any other time since the late Pre-Cambrian.

Atomic Physics

By THE RIGHT HON LORD RUTHERFORD, O M , F R S , Cavendish Professor of Physics, University of Cambridge

THE past twenty-five years has been a period of unexampled activity in physical science, and has witnessed a series of important discoveries which have widely extended our knowledge of the nature of the atoms and the interaction between matter and radiation. On looking back, we can see that the direction of advance was greatly influenced by three fundamental discoveries made at the end of last century—the discovery of X-rays, of radioactivity and of the electron The proof of the wave-nature of the X-rays in 1913 led to the development of simple methods for studying the X-ray spectra of the elements, and thus gave us important information on the arrangement of the electrons deep in the atom and their frequency of vibration. The study of the radioactive bodies had disclosed that they were undergoing spontaneous transformation and gave us for the first time an idea of the enormous forces which must exist within the structure of the atom. Sir J. J. Thomson early recognised that the electron must be a fundamental constituent in the structure of all atoms, and had devised methods for estimating the number of electrons present in each atom.

The nuclear theory of the atoms, based on experimental evidence of the scattering of α-particles by matter, belongs to the beginning of the period under review The proof by Moseley that the properties of an atom are defined, not by its atomic weight, but by its atomic or ordinal number, was an outstanding step in advance It was shown that the atomic number was a measure of the number of units of resultant charge carried by the nucleus and also a measure of the number of electrons surrounding the nucleus A relation of extraordinary simplicity was thus seen to connect all the elements—a relation which has governed all subsequent advances in our knowledge of the elements

The proof that the chemical elements are complex and in general consist of a number of isotopes of different masses was an important advance This conception, which we owe to Soddy, had its origin in the study of the chemical properties of the radioactive elements In the nuclear theory, isotopes represent atoms of identical nuclear charge but different masses. They should have the same chemical properties, apart from mass, and

almost identical spectra Ashton showed in 1919 that the masses of the individual isotopes were nearly whole numbers in terms of O = 16. This whole number rule, while very convenient as a guide, is only approximate The accurate determination of the masses of the isotopes is of first importance, for it serves in a sense as a measure of the energy stored up in the atom and thus enters into all calculations which have to do with the transmutation of atoms

More than 250 species of atoms are now known, and even the lightest atom—hydrogen—has been shown in the last few years to consist of three isotopes of masses 1, 2 and 3 The isotope of mass 3 was first observed by Oliphant in transmutation experiments and has since been found to be present in ordinary hydrogen in about one part in a hundred million The discovery of the isotope of mass 2, now called deuterium, by Urey, has had important consequences, since it can readily be separated in a nearly pure state, and made use of in many physical and chemical experiments

This period has also seen the beginning and ultimate success of the application of quantum ideas to the explanation of the origin of the spectra of the elements, both X-ray and optical This wonderful advance, which we owe largely to the work of Bohr, is one of the most spectacular triumphs of this age Within less than a decade, the intricacies of the varied spectra of the elements were unravelled and explained along general lines. At the same time, there followed a complete understanding of the underlying meaning of the periodic table of the elements by taking into account the way in which electrons are grouped round a nucleus.

The application by Bohr of the quantum theory for the explanation of spectra was at first beset with many difficulties and ultimately led to the development of a new mechanics—the wave-mechanics—so closely associated with the names of de Broglie, Heisenberg, Schrödinger, Born and Dirac This has proved successful in giving an explanation not only of the complexities of the spectra of the elements but also of many of the most recondite problems of atomic physics. It has been applied to account in a general way for certain radioactive relations like the Geiger-Nuttall rule, while Gamow has utilised the theory to account for the artificial transformation of elements by particles of very low speed which on classical mechanics had no possibility of entering a nucleus.

The essential correctness of the ideas underlying the wave-mechanics has been verified by the direct experiments of Davisson and Germer, G. P. Thomson and Stern, by observing the diffraction effects produced by electrons and atoms when they fall on a crystal.

It will be seen that the past twenty-five years has been mainly occupied in an intensive study of the properties and structure of the atoms of the elements An enormous new territory of knowledge has been opened up and surveyed in detail. While the first idea of the quantum theory of radiation had been advanced by Planck in 1905 to account for the distribution of energy in the spectrum of a hot body, it was not until the period under review that the full significance and fruitfulness of the new conception was generally recognised It was early applied by Einstein to explain the photo-electric effect and by Nernst and Debye to account for the variation of specific heat with temperature, but its full importance was not realised until Bohr's work on the origin of spectra The interchange of energy between a quantum and an electron was made clear, while the interaction with an electron, which gives rise to scattering, was examined and explained by Compton on the quantum theory

Another strange type of interaction between radiation and matter has recently been discovered. When a gamma-ray of high quantum energy interacts with the intense electric field near a nucleus, the energy of the gamma-ray may be transformed with the appearance of an electron pair—one positive and the other negative Since the mass energy of the electron pair is about one million volts, this type of interaction only occurs when the quantum energy of the gamma ray exceeds this value The passage of high-frequency radiation through matter of high atomic weight is one of the simplest ways of producing positive electrons for study in the laboratory

Only brief reference can be made to two important problems which have occupied the attention of many investigators throughout the world during the last few years, namely, the cosmic rays and the transformation of matter. The existence of a very penetrating radiation in our atmosphere was first shown by Kolhörster, and the properties of this radiation have been examined by Millikan, Clay, A. H. Compton, Blackett and many others. When we consider the minuteness of the ionising effect of this radiation in an electroscope near the earth, much skill and technical ability have been required to make accurate observations often under difficult conditions. The investigations have been world-wide, and have involved measurements in deep water, on land and sea, on high mountains and at different heights in our atmosphere, extending far into the stratosphere.

It now seems likely that the main radiation consists of a stream of fast electrons both positive and negative possibly also protons with an admixture of high frequency radiation It is believed that some of the particles have energies so high as 10^9 volts and a few as high as 10^{10} volts —energies of a different order of magnitude from those to be expected from the transformation of atoms Naturally there has been much speculation as to the origin and nature of this extraordinary radiation which appears to come either from the confines of our atmosphere or from the depths of outer space The conditions under which particles can reach such gigantic energies constitute one of the outstanding unsolved problems of physics

While the natural transformation of the radioactive elements was made clear in 1903 the proof of the transmutation of many of the stable chemical elements by artificial methods belongs to the past quarter of a century The study of these transformations has been very fruitful leading to the discovery of three important entities in the structure of the atom—the proton neutron and the positron the counterpart of the negative electron of small mass

In order to produce a veritable transformation of an element it is necessary to change its nuclear charge or its mass or both together The chief method employed for this purpose is to bombard the element under examination by fast particles like protons neutrons or α particles Occasionally one out of a great number of these particles may happen to penetrate a nucleus and be captured by it The resulting nucleus may be unstable and break up with explosive violence hurling out a fast particle or particles and sometimes emitting high frequency radiation The residual nucleus may be either a stable element or an unstable element which behaves like a radioactive body The production of artificial radioactive bodies in this way by α particle bombardment was recently observed by M and Mme Curie Joliot

The first successful experiment on transmutation was made in 1919 when nitrogen bombarded by α-particles was found to be transformed with the emission of fast protons Rutherford and Chadwick found that about a dozen of the lighter elements suffered a similar type of transformation under the same conditions In order to extend these observations investigations were begun often on a large scale to produce intense streams of fast particles of different kinds to be used for bombarding purposes Cockcroft and Walton first showed that marked transformations could be produced in the light elements lithium and boron when they were bombarded by streams of fast protons accelerated in a discharge tube Lawrence, in California used an ingenious method of obtaining fast particles by multiple acceleration in a magnetic field and was able to obtain swift particles of energies as high as two million volts He found that the ions of heavy hydrogen of mass 2 were even more effective than protons in producing new types of transformation in a number of elements In some cases neutrons as well as protons and α particles appeared as a result of the transformations

The discovery of the neutron by Chadwick has proved of great importance not only in simplifying our ideas of the structure of nuclei but also as an extraordinarily effective agent in bringing about the transformation of many elements as was first shown by Feather and Harkins Fermi and his co workers in Rome made an important advance when they showed that neutrons could enter freely into the structure of even the heaviest nuclei in many cases leading to the production of artificial radioactive bodies which broke up at a characteristic rate with the emission of fast negative electrons More than fifty of these radioactive bodies are now known

By these transformation methods it has been found possible to build up heavier atoms from lighter to break some atoms into fragments and to produce radioactive isotopes in great numbers New and unsuspected stable isotopes of the elements like H^3 He^3 and Be^8 have been brought to light and gamma rays of much higher frequency than those from the natural radioactive bodies have been observed

The rapid advance of our knowledge of nuclear transformations has been in no small part due to the development of new technical methods of attack for example the automatic method of counting α particles and protons devised by Wynn Williams the Geiger Muller tube for recording positive and negative electrons and that wonderful instrument the cloud chamber devised by C T R Wilson The development of fast diffusion pumps by Gaede has made possible the rapid production of high vacua and the application of high potentials to discharge tubes

Our ideas of the structure of atomic nuclei are still in a very tentative state but it is generally believed that the proton and neutron are the primary building units The exact relation if any between the proton and neutron is still uncertain Some believe they are mutually convertible in a nucleus by the gain or loss of an electron and that even negatively charged protons may be formed Much more information is required before we can hope to reach a satisfactory explanation of nuclear structure and any detailed theory applicable to the nucleus is probably far distant

Isotopes

By DR. F W ASTON, F.R.S., Trinity College, Cambridge

THE subject of isotopes is particularly suitable for inclusion in this special issue of NATURE, for it is just twenty-five years since Soddy published the first valid proof of their existence The earlier speculations of Crookes and others had been found to rest on unsound observations. Discussing apparent chemical identities among the products of radioactivity, Soddy said "Chemical homogeneity is no longer a guarantee that any supposed element is not a mixture of several of different atomic weights, or that any atomic weight is not merely a mean number" The basis of his evidence was the law connecting radioactivity and chemical change, in the discovery and enunciation of which he played so prominent a part This law asserts that a radioactive element when it loses an α-particle goes back two places in the periodic table, when it loses a β-particle it goes forward one place It follows that by the loss of one α-particle followed by two β-particles, the atom, though weighing four units less, will have regained its nuclear charge and returned to its original place.

Such changes result in bodies to which Soddy applied the following words "The same algebraic sum of the positive and negative charges in the nucleus when the arithmetical sum is different gives what I call 'isotopes' or 'isotopic elements' because they occupy the same place in the periodic table They are chemically identical, and save only as regards the relatively few physical properties which depend upon atomic mass directly, physically identical also" Since the radioactive disintegration of uranium should result in lead of atomic weight 206, and that of thorium in lead of atomic weight 208, Soddy maintained that the lead found in uranium minerals should be lighter and that in thorium minerals heavier than ordinary lead, of atomic weight 207 2.

The idea that ordinary elements could consist of atoms of different mass received great opposition, for it appeared quite incompatible with such facts as the constancy of chemical atomic weight, the apparently perfect homogeneity of elementary gases, and the almost incredible invariability of such accurately measurable constants as the electrical conductivity of mercury independent of its source. Nor was it at first supported by the only available method of comparing the weights of individual atoms, Sir J J. Thomson's parabola analysis of positive rays, which was then being perfected, for such elements as hydrogen, carbon, nitrogen and oxygen gave only single parabolas. Neon, on the other hand, gave two parabolas, the one expected at 20 and a second fainter one at 22. Experimental evidence indicating partial separation of the hypothetical constituents of this element by diffusion was obtained in 1913, and when the War stopped work, there were several lines of reasoning suggesting that it consisted of isotopes, but none of these was sufficiently strong to carry conviction

During the War, Soddy's prediction concerning the atomic weights of leads from uranium and thorium minerals had been triumphantly vindicated by some of his most severe critics, the experts in chemical atomic weights, and it was realised that the most satisfactory proof of the isotopic nature of neon could be obtained by much more accurate analysis of its positive rays An instrument using a focusing device capable of a resolution of 1 in 130 and an accuracy of 1 in 1,000 was set up in 1919 by the writer and called a 'mass-spectrograph', a term which has now been extended to all devices capable of analysing mass-rays This instrument not only proved that neon was a mixture of atoms having weights, or mass numbers, 20 and 22, but also that chlorine consisted similarly of isotopes 35 and 37, and indeed that the majority of all elements were complex Thus krypton, the first element shown to be multiple, had six isotopes, 78, 80, 82, 83, 84, 86 Of the greatest theoretical importance was the fact that the weights of the atoms of all the elements measured, with the exception of hydrogen, were whole numbers to the accuracy of measurement This 'whole number rule' enabled the simple view to be taken that atoms were built of two units, protons and electrons, all the former and about half of the latter being bound together to form the nucleus

The analysis of the elements advanced rapidly, Dempster in America discovering the isotopes of magnesium, calcium and zinc by means of an instrument of his own design having magnetic focusing. By 1925, when the first mass-spectrograph was dismantled to be replaced by a more powerful one, information on the isotopic constitution of more than half the elements had been obtained. The new instrument was designed primarily for measuring the minute variations of the masses of atoms from the whole number rule, and had a resolving power ample for the heaviest elements. By its means the search for

isotopes has been carried on until a few months ago

The difficulty of obtaining the necessary rays for analysis varies enormously from element to element Two main devices are employed the ordinary gas discharge which requires the element to be volatile or form suitable stable volatile compounds, and the anode ray discharge, in which the halide or other compound of the element is treated as the anode in a discharge at low pressure The inert gases are particularly suitable to the first method, the alkali metals to the second, other groups of elements being intermediate The largest group recently investigated was that of the rare earths These yielded to anode ray methods, and during the work some thirty new isotopes were discovered

From the point of view of the identification of the more abundant isotopes, our knowledge is nearly complete Of the more common elements all but four—palladium, iridium, platinum and gold—have yielded definite information on their isotopic constitution The resistance of these four is due to their chemical properties, which make the production of their rays peculiarly difficult In all, some 247 stable isotopes are now known, of which seven were discovered by observations on optical spectra, and have since been confirmed by the mass-spectrograph This large assembly shows many empirical laws, of which perhaps the most remarkable is that no odd numbered element, with the possible extremely rare exception H^3, has more than two isotopes Even elements are not so limited The most complex element so far observed is tin, with eleven isotopes ranging in mass number from 112 to 124 One of the most astonishing results is that, for practically every natural number up to 210, a stable elementary atom is known, many are filled twice over and a few three times with 'isobares', that is, atoms of the same weight but different chemical properties Schemes of tabulation of all the known species have led to the prediction of isotopes and to theories of nuclear structure to account for their occurrence

Instead of the original view that the nuclei of atoms consisted of protons and electrons, it is now considered more likely that they are built of protons and neutrons In either case the binding forces holding the particles together must represent loss of energy, that is, loss of mass. Hence it is that the atom of hydrogen has abnormally high mass, and that the accurate determinations of divergences from the whole number rule are of such profound theoretical importance As has been stated, my second mass-spectrograph was designed for this and found capable of an accuracy in favourable cases of 1 in 10,000. The atom of oxygen, 16, was chosen as standard and the percentage divergencies called 'packing fractions', were determined for a large number of elements These when plotted against mass number were found to fall roughly on a hyperbolic curve Our knowledge in this field has been notably increased by the brilliant work of Bainbridge, who, by means of a powerful mass-spectrograph of original design set up at Swarthmore, discovered new isotopes of tellurium, rectified results on zinc and germanium and made many of the most accurate comparisons of mass so far known

The relative abundance of the isotopes of an element can be measured in several ways, the most general being by photometry of mass spectra From this and the masses of the isotopes it is easy to calculate the mean atomic weight This with proper corrections can be used to check the chemical atomic weight During the past six years, nearly every atomic weight has been determined by this purely physical method, which has the great advantage of being, in general, independent of purity and requiring an almost infinitesimal quantity of material

The masses of the atoms H^1, C^{12}, N^{14} and O^{16} as determined by the second mass-spectrograph and published in 1927 agreed to 1 part in 10,000 with the accepted chemical atomic weights of those elements, but shortly after, observations on band spectra made by Giauque and Johnson showed the presence of heavier isotopes 17 and 18 in oxygen Their abundance determined by Mecke was such that the chemical unit of atomic weight O was about 2×10^{-4} greater than the physical one, O^{16}. Carbon and nitrogen were found later to possess heavier isotopes, and Birge pointed out that to satisfy the values hydrogen must have them also Urey took up the problem and, happily unaware of the real uncertainty in the figures concerned, with the collaboration of Brickwedde and Murphy fractionated liquid hydrogen and proved by examination of the Balmer lines that H^2 was present Washburn showed that its heavier atoms could be concentrated by electrolysis of water This method was developed so rapidly and brilliantly by Lewis that, soon after its discovery, pure 'heavy water' had been obtained in appreciable quantity

The isotope of hydrogen of mass 2 cannot be treated as a normal isotope Its exceptional difference in mass enables it to be separated with comparative ease in a pure state It has been given the name deuterium, symbol D, and heavy water (D_2O) is now obtainable in quantity at reasonable prices, one of the most surprising and interesting reagents in the whole history of science.

Induced Radioactivity

By DR C. D. ELLIS, F.R.S., Lecturer in Physics, University of Cambridge

IT is just over a year since M and Mme Curie-Joliot announced that they had succeeded in producing radioactive atoms of low atomic number. In their first experiments they discovered that, when aluminium was bombarded by α-particles, a radioactive isotope of phosphorus was produced according to the reaction

$$_{13}Al^{27} + {}_{2}He^{4} \rightarrow {}_{15}P^{30} + {}_{0}n^{1}$$

The behaviour of this radio-phosphorus was quite analogous to that of the naturally occurring radioactive elements, except that instead of β-rays, that is negative electrons, positrons were emitted, resulting in the formation of a known stable isotope of silicon

$$_{15}P^{30} \rightarrow {}_{14}Si^{30} + \overset{+}{\epsilon}.$$

The half period of the radioactive decay was about 3·2 minutes

Similar results were found to occur using boron or magnesium instead of aluminium. With the ordinarily available α-particle sources, the amounts of these radioactive bodies that are produced is extremely small Even if all the α-particles emitted from the source are arranged to hit the aluminium, the resulting radioactive phosphorus will have only about one millionth to one ten-millionth of the activity of the source These small intensities are responsible for the main difficulties in the experiments, which would be impossible but for the delicate counting devices devised by Geiger

Since the initial discovery of the Joliots, other methods, as suggested in fact by them, of forming radioactive elements have been discovered Protons, deuterons and neutrons have all been found to lead to nuclear reactions which produce radioactive products. This is not the occasion to give a list of all the new radioactive isotopes that have been discovered. It will suffice to say that more than fifty have already been identified One important aspect of this may be noted Aston's work in furnishing a list of all the stable isotopes at least made possible speculations about the structure of nuclei—why certain combinations of protons and neutrons did occur and others did not. His later and more delicate work on the exact masses of the isotopes gave information about the energy of binding of these nuclei and provided a basis for quantitative theories Now, directly following from the Joliots' discovery, this field is suddenly enriched by a large number of new nuclei about which, by appropriate experiments, we may reasonably hope to obtain similar information Above all, this discovery must be considered as a remarkable extension of the possibilities of our knowledge

It is interesting to consider the relation of these new radioactive isotopes to the already known stable isotopes It is clear that certain combinations of protons and neutrons can form permanent nuclei The criterion of this permanency lies in the fundamental laws of interaction of proton and neutron, but the question whether a given nucleus is absolutely permanent or radioactive is connected with what might be termed the possibility of existence of neighbouring nuclei. Whether a given nucleus A is stable or radioactive depends, so far as our present knowledge goes, simply on the question whether the reaction $A \rightarrow B + C$ is endothermic or exothermic, B and C being other possible nuclei In practice, the only reasonable possibilities for C are proton, neutron, α-particle, electron or positron In the natural radioactive elements, C is either an α-particle or an electron; in the newly discovered radioactive elements, C is either an electron or a positron As yet, no case is known of induced radioactivity with emission of a heavy particle

In a general way, it is easy to see the factors which determine whether positrons or electrons are emitted Assuming that nuclei are built up of combinations of protons and neutrons, an examination of the list of the known stable isotopes shows clearly that permanently stable nuclei are only formed when the ratio of the number of neutrons to protons lies within a narrow range Isotopes with either a smaller or greater neutron/proton ratio do not occur naturally Now the addition of an α-particle (two neutrons + two protons) and the emission of a neutron is, in effect, an addition of one neutron and two protons, and means, therefore, a lowering of the neutron/proton ratio. If this ratio for the new element lies outside the stability range, the element will be radioactive, and the change will clearly be in the direction of raising the neutron/proton ratio. This can be effected by the switch of a proton into a neutron with emission of a positron On the other hand, if the initial absorption of an α-particle causes the emission of a proton, the situation is exactly reversed and a radioactive element so formed will emit negative electrons accompanied by a nuclear switch of a neutron into a proton. As an example of this latter process we may take magnesium bombarded by α-particles Magnesium has three stable

isotopes and one of them undergoes the following reaction.

$$_{12}Mg^{25} + _{2}He^{4} \rightarrow _{13}Al^{28} + _{1}H^{1}.$$

The aluminium isotope so formed is radioactive with a period of two and three quarter minutes, with emission of negative electrons

The use of protons and deuterons to cause nuclear reactions leading to radioactive products has already been referred to but is of especial interest, since the intensity of the bombarding beams is here under control, and by sufficient technical application can be largely increased Already Lawrence has produced a radioactive body in amounts comparable with that of the naturally occurring radioactive substances. A particularly interesting example is that of sodium bombarded by deuterons, when the following reaction occurs.

$$_{11}Na^{23} + _{1}D^{2} \rightarrow _{11}Na^{24} + _{1}H^{1}.$$

This new isotope of sodium disintegrates under emission of β-particles with a period of fifteen and a half hours The β-particles are not particularly energetic, having an upper limit of energy of only about one million volts, but an intense high-frequency γ-radiation of about five and a half million volts is also emitted Using 1 microampere of 1·7 million volt deuterons for one hour gave already a two hundredth of a millicurie of radioactive material This is an amount the effects of which can be detected by ordinary ionisation methods, and there is every reason to believe that it will be possible soon to increase the yield very greatly

A great number of interesting investigations will be rendered feasible when it is possible to obtain in quantity a radioactive body such as this with a conveniently long period and emitting such high-frequency γ-radiation.

The most striking results, from the point of view of the number of new radioactive elements produced, have been obtained by Fermi, using neutrons as bombarding particles. The neutrons for these experiments are obtained by allowing α-particles to fall on beryllium, in practice by filling a small tube with beryllium and a certain quantity of radon. The number of neutrons is only about one hundred thousandth of the number of α-particles emitted by the source, but their efficiency in producing nuclear reactions is much greater. In fact, a large percentage of the neutrons which hit the nucleus produce an active atom. These experiments have also a far greater range than those using α-particles or protons, since the absence of charge on the neutron removes any distinction between light and heavy elements. The new radioactive isotopes formed in this way are spread fairly uniformly throughout the periodic table, for example, active bodies are formed from fluorine and magnesium, and also from thorium and uranium In general, for light elements the process of activation consists in the capture of the neutron and simultaneous emission of an α-particle or proton The resulting nucleus has then a higher neutron/proton ratio than corresponds to stability, and the necessary balance is re-established by the radioactive change of a neutron into a proton inside the nucleus with emission of an electron For elements of higher atomic number, the chance of the initial ejection of a positively charged α-particle or proton is diminished by the stronger attractive field of the nucleus, and the initial process is more likely then to be just a simple capture of the neutron, again leading to an active nucleus with too high a neutron/proton ratio

There are several points about the processes involved in the direct capture of a neutron which are not at present easy to understand, but it is plausible that the probability of capture should increase as the energy of the neutron is decreased Fermi has in fact shown that the efficiency of production of some radioactive elements may be increased ten to one hundred times by surrounding the source and target by paraffin or water during bombardment The primary neutrons emitted from the source are slowed down by elastic collisions with the hydrogen nuclei, and in this state are more easily captured by the nuclei of the bombarded substance

Finally, as an example of the flexibility of these methods of producing new nuclei, we may consider the formation of a certain radioactive isotope of aluminium, $_{13}Al^{28}$ This can be formed now in no less than five distinct ways, starting from different substances and using different bombarding particles

Neutrons fired on to either aluminium, silicon, or phosphorus form this body according to the schemes.

$$\begin{aligned} &_{13}Al^{27} + _{0}n^{1} \rightarrow _{13}Al^{28} \\ &_{14}Si^{28} + _{0}n^{1} \rightarrow _{13}Al^{28} + _{1}H^{1}. \\ &_{15}P^{31} + _{0}n^{1} \rightarrow _{13}Al^{28} + _{2}He^{4} \end{aligned}$$

One can also use deuterons on aluminium or α-particles on magnesium, the latter reaction having already been mentioned in another connexion·

$$\begin{aligned} &_{13}Al^{27} + _{1}D^{2} \rightarrow _{13}Al^{28} + _{1}H^{1} \\ &_{12}Mg^{25} + _{2}He^{4} \rightarrow _{13}Al^{28} + _{1}H^{1} \end{aligned}$$

In every case the same final product is obtained, which emits β-particles to form $_{14}Si^{28}$ and has a period of about two and three quarter minutes

X-Ray Crystal Analysis

By SIR WILLIAM BRAGG, O.M., F.R.S., Fullerian Professor of Chemistry, Royal Institution, and Director of The Davy-Faraday Research Laboratory

THE development of the analysis of crystal structures by means of X-rays has fallen entirely within the period which the citizens of the British Commonwealth are now reviewing. Soon after the beginning of the present reign, a group of German scientific workers made the primary and fundamental discovery. But although the first step was taken abroad, the immediate and consequent advances were made in England, and throughout the whole twenty-five years British workers have taken a full share in the development of a subject which has now grown to extraordinary magnitude. The story of it falls happily, therefore, on the ears of those who now celebrate the King's Jubilee and consider the advances in knowledge which have been made during his reign.

The first experiments were made in Munich in 1912 and have been described in a fascinating manner by Friedrich, who helped to conduct them; his account is to be found in *Die Naturwissenschaften* for April 22, 1922. As has been pointed out by W. L. Bragg ("The Crystalline State", p. 271) the conditions in Munich at that time were peculiarly favourable to the event which gave rise to a new branch of science. Laue, a great mathematician, was profoundly interested in interference phenomena, and Sommerfeld, a great mathematical physicist, in the nature of X-rays and their excitation by the stopping of cathode rays, while Groth was the world's most famous authority on crystallography. The actual incident which precipitated the discovery was a doctor's dissertation by Ewald, who at that time had undertaken, under Sommerfeld's guidance, the study of the passage of light waves through a crystal, considered as a regular arrangement of scattering atoms. When discussing Ewald's problem, Laue was led to ask what would happen if the waves were so short that the wave-length was less than the interatomic distances in the crystal. He realised that spectra should be formed and that waves so short as to be diffracted in this way would be X-rays. An informal discussion on the possibility of observing this phenomenon took place after one of the colloquium meetings and Friedrich, who was then Sommerfeld's assistant, volunteered to carry out some experiments. Success came after several failures. Friedrich gives a vivid picture of his feelings when he saw the diffraction picture in the developing dish.

At that time the writer of this review was contending strongly that the X-rays must be regarded as corpuscular, if their general behaviour, and in particular their relations to cathode rays, were to be explained systematically. It did not occur to him at that time that undulatory and corpuscular theories could be held and worked simultaneously. Consequently, the new experiment seemed to be fatal to his views. It is now understood, of course, that the two theories must go in double harness, even if they do not always seem to pull together.

Naturally perturbed at the apparent contradiction, the writer suggested to his son, who had just completed his course at the University of Cambridge and was looking for a problem to attack, that he should study the new experiment and see if any reconciliation could be found. The conclusion that Laue was essentially correct was soon found to be inevitable. At the same time, it appeared to the young worker that Laue's explanation of the details of his zinc blende photographs was unnecessarily complicated. He found it simpler to approach the problem with the idea that electromagnetic pulses, equivalent to 'white light' in the X-ray region, were reflected from the crystal planes. This was suggested by the behaviour of the spots in the photograph when the crystal was tilted and by their shape. He was then able to draw certain conclusions as to the structure of zinc blende. This result was published in November 1912. The Laue photographs of sodium chloride and potassium chloride were found to be even simpler than that of zinc blende, so that all the details of their structures could be found. These two were the first crystals to be analysed.

Meanwhile, the writer at Leeds, and Moseley and Darwin at Manchester, examined the reflected beams of X-rays, using ionisation chamber and absorbing screens, and found that they had all the characteristic properties of the incident beam. From these researches came the X-ray ionisation spectrometer, which showed not only the 'white' radiation reflected over a wide range of angle but also the peaks of the characteristic line spectrum of the material of the target in the X-ray tube.

The discovery of the line spectrum had two results. In the first place, it made crystal analysis enormously more powerful. Several fairly simple structures were quickly solved by its means, such

as zinc sulphide, iron pyrites, fluorspar and calcite. In the second place, the high-frequency spectra of the elements could be measured accurately. This led to the brilliant and well-known generalisation of Moseley who, by using an extended range of anticathodes, was able to formulate the laws relating frequency to atomic number. Moseley's death at Gallipoli in 1915 was a sad blow to the development of a new science.

The outbreak of War in 1914 put an end to most of the researches in crystal analysis then proceeding. In the two short years great progress had, however, been made. The determination of crystal structure had begun. The ionic, or heteropolar, character of many crystals had been discovered. It is to be observed that in some of these early determinations the X-rays were called on for nothing more than a simple and ready decision between structures already suggested by other considerations. But the decision was final and very helpful The measurements of the intensities of the rays reflected from the various crystal planes had not yet come to play the important part that it does to-day. The measurements were used to determine the geometrical quantities of the crystal, the size of the unit cell and a few important data as to the relative positions of the elements in it Intensities were measured in certain cases, but no great accuracy was required Indeed, the technique was barely able to supply it. Moreover, there was the difficult question of the interpretation of the meaning of intensity measurements Darwin had, indeed, covered almost the whole ground of the theory of X-ray reflection. He distinguished between the perfect crystal, which is indeed a rarity, and the so-called 'mosaic crystal', which consists of an assemblage of small and more perfect crystallites, mutually aligned with greater or less accuracy. But his results were not put to their full use.

In some of the neutral countries work was carried on, and important results were obtained. In Sweden, Siegbahn developed a fine school devoted to spectrum measurements in which extraordinary accuracy was obtained. In Switzerland, Debye devised the 'powder' method which could be applied to the analysis of materials so finely subdivided that the crystalline character could not be observed even with the aid of the microscope. The crystalline character of colloidal suspensions, for example of gold, was a discovery of great interest. In America, Hull made use, independently, of the same method. The consequence of this advance was the inclusion of a vast number of substances, hitherto not recognised as crystalline, within the range of the X-ray analysis.

As soon as the laboratories could settle down to work again, after the War was over, the new subject was energetically studied all over the world and progress was rapid It was natural that in the first place efforts should be devoted to the task of shaping a new crystallography. The old had been founded almost entirely upon the external characteristics of crystals , the new gave insight into the body of the crystal and was obviously much more fundamental. The discoveries that had already been made gave promise of various useful generalisations, and these called for careful examination. Three main types of structure were to be recognised They may be illustrated from the work done before the War. There was the heteropolar type represented by rocksalt, in which ions were arranged so that each ion of one sign was surrounded by a certain number of ions of the contrary sign, all equally related to it. There was the homopolar type represented by diamond, in which the atoms were held together by the valency bonds of the chemist, now called co-valent bonds. In the diamond and other structures such bonds linked the crystal together into one whole. We know now that in most organic crystals only the atoms of each molecule are so linked together, the ties between molecule and molecule being the comparatively weak forces of Van der Waals Lastly, there were the metals such as, for example, aluminium, in which the atoms were held together by what may be termed an electronic cement.

In all these types one common and most important feature at once emerged The atoms or ions retained their characteristic dimensions in whatever structure they were embodied The first tables of atomic or ionic radii were drawn up by W L. Bragg, and in Finland by Wasastjerna. On these considerations Goldschmidt and his assistants reared a 'geochemistry' which showed how largely the various forms of crystal structure were governed by rules of geometry. To Niggli we owe the idea of a systematic deduction of the 'space-group' by means of X-ray data.

The most important constituents of the earth's crust are the silicates. Their immense variety of structure and chemical constitution had long presented an analytical problem which seemed to be insoluble by the older methods. W. L Bragg and his colleagues at Manchester have been successful in resolving their complications. The oxygen atoms, it seems, play a leading part in the structure. They form the bricks, laid as regularly as possible ; while the other constituent atoms, used somewhat indiscriminately, bind the whole together. In the course of this work it has been necessary to

measure the intensities of the reflections from the various crystal planes, determining their values relative to the primary rays The electron distributions within the atoms also required evaluation, for which the theoretical work of Hartree and the experimental work of James and others proved invaluable. Also, at the University of Manchester a study of alloys has been very successful, Bradley's determinations of γ-brass and α-manganese leading the way At the present moment this branch of the subject is developing rapidly , by its means new insight is being gained into many metallurgical problems To the study of alloys, Westgren in Sweden contributed much pioneering work Another outstanding contribution has been Hume-Rothery's theory that the electron-atom ratio is a major factor in determining the type of an alloy structure.

Crystals composed of the complicated molecules of organic substances require special treatment if complete solutions are aimed at. It can be shown that every reflection which a crystal yields implies a harmonic variation of electron density, the magnitude of which corresponds to the intensity of the reflection. By measuring the absolute intensities of one or two hundred reflections, and summing up the implied harmonic variations in the manner of a Fourier series, a picture of the distribution of electron density is obtained The result is usually displayed in the form of a contour map, showing the densities projected upon some principal plane The atoms are clearly outlined and their positions can usually be determined with great accuracy. Very interesting determinations have been made in this way by J. M Robertson, Iball, Miss Knaggs in the Davy-Faraday Laboratory, by Wyckoff in America and others Here again there emerges a remarkable constancy in the distances between atomic centres · given a pair of atoms and the character of the bond, single, double or treble, the distance that separates them seems to be always the same, in whatever structure they enter In this case there is an added constancy in the orientations of the bonds in general : though in special circumstances variations may be forced upon them.

One of the most remarkable of the organic substances is the carbon chain which is the essential part of the paraffins, fatty acids, alcohols and the like. Its complete elucidation is due to Müller, Shearer and Piper in Great Britain, to M. de Broglie, Friedel and Trillat in France, and to others. The frequency with which the long chain appears in the construction of Nature is extraordinary and suggestive. It may be all of carbon, as in the cases just quoted : or it may include nitrogen as in the proteins, or as in cellulose it may consist of a series of linked rings each formed of carbon and oxygen

Some of the most remarkable investigations in organic substances have been made by Bernal, his subject being the vitamins and other biological structures. In this way the X-ray analysis is now contributing to biology

No one expected, when the new study began, that such a complicated substance as cellulose would have yielded to treatment but Mark, and Polanyi in Germany, and many others have found it possible to gain much useful information from the X-ray photographs, ill-defined as they are in comparison with those of crystals that can be recognised as such This work was, of course, inspired by the great importance of cellulose in many industries Later, Astbury, at Leeds, was able to solve the curious problem of the extensibility of keratin and other proteins He was able to show, for example, why wool is elastic and silk is not, basing his explanation on the determination of their fundamental structure. Recently he has explained in the same way the extensibility of nerve and muscle.

Naturally the determination of crystal structure has given a great opportunity to the mathematical physicist to formulate the laws which govern it, and to trace their actions The new system of wave-mechanics introduced by de Broglie and Schrödinger has been brought to bear, and much interesting work has already been done To this Born, Hund, Hückel in Germany, Hartree, Fowler, Lennard-Jones in England, Compton, Pauling and Slater in America, and many others in all parts of the world have made contribution.

Lastly, a word must be said in respect to the technical applications of X-ray analysis These have been many and varied. A section of the staff of the National Physical Laboratory under Shearer has been engaged in the study of various problems submitted by industry. A vast amount of research has been carried out in various places on the deformation of metal crystals, and the alterations in structure and properties due to cold-working. In this Polanyi has been the pioneer. In England, G. I. Taylor has been a chief contributor, while Gough at the National Physical Laboratory has concerned himself chiefly with the special question of the nature of metal fatigue.

This short sketch does but touch on a few of the principal matters that have formed part of the development of a subject now grown to very large dimensions ; and it has only been possible to refer by name to a few of the many who have contributed thereto.

Low Temperature Research: Methods and Results

By PROF F. A LINDEMANN, F R S , Professor of Experimental Philosophy, University of Oxford

FEW branches of scientific research have developed more rapidly in the course of the last quarter of a century than the investigation of the properties of matter at low temperatures Twenty-five years ago such problems seemed of comparatively slight fundamental interest One knew, of course, that the electrical conductivity of metals increased with falling temperature Dewar had shown that the specific heats of solids diminished somewhat But no striking new phenomena were expected, and no exciting theoretical developments appeared likely to arise from research in these regions. Low-temperature work had gone out of fashion In Leyden alone, in the magnificently equipped laboratory of Kamerlingh Onnes, a series of elaborate and most accurate measurements of all sorts of properties of a series of substances attested that interest in this branch of knowledge was not extinct

As so often happens, it was from quite an unexpected quarter that interest in the subject was revivified In 1905 Nernst had enunciated his famous third law of thermodynamics, according to which, in any thermodynamic process, at the absolute zero the rate of change of affinity with temperature equals the rate of change of the heat content. To test this, the atomic heats near the absolute zero had to be ascertained, and to this end, with characteristic energy, Nernst turned over his Berlin laboratory to low temperature research. It very soon emerged, somewhat unexpectedly, that at low temperatures the atomic heats of all solids seemed to tend to zero. The kinetic implications of this discovery were far-reaching.

Already in the year 1900 Planck had enunciated his famous law of complete radiation. In order to derive this, it had been necessary to assume that linear oscillators obeying Maxwell's equations could only absorb or emit radiation in quanta the energy of which was proportional to their frequency But since it followed from Kirchhoff's law that the same law of radiation must emerge whatever the radiating entities, nobody had felt constrained to attach great importance to Planck's revolutionary presupposition. True, linear oscillators on his premises would lead to a law agreeable to experiment, but then no one really believed that the radiation from a hot body was due to linear Hertzian oscillators. Thus Planck's epoch-making assumption was treated with the comfortable indifference with which one slurs over the details of processes introduced in so many imaginary thermodynamic cycles

Even when Einstein pointed out in 1907 that the variation with the temperature of the specific heat of the diamond could be accounted for by applying Planck's premise to the atoms, it aroused little interest For the diamond had long been known to form an exception to Dulong and Petit's law, and one was accustomed to attribute the anomaly to polymerisation or some similar question-begging explanation

When it appeared that not only the atomic heat of the diamond, but also that of all solids, diminished at low temperatures, the matter took on a new complexion , and after it had been shown that the atomic heats of all simple substances when plotted against the temperature could be represented by the same formula, containing only one parameter characteristic of the substance, it became clear that, far from being a special assumption introduced in an imaginary case—unimportant, since any permissible imaginary process must lead to the right result—Planck's premise was a very vital physical fact

If actual atoms in a space-lattice held in position by their mutual attractions and repulsions could only take up or lose energy in quanta proportional to their frequency, then there must be something radically wrong with the whole basis of classical dynamics The atomic heat measurements at low temperatures seemed to prove the major premise , and though we have now learnt to express it in the form that there are only a finite number of distinguishable states within a given energy range for the atoms in a crystal, the minor premise has finally won general acceptance Differences may still exist as to the best way of introducing the quantum hypothesis. Nobody would to-day deny that some definite break with the classical point of view was inevitable.

Until 1933 the methods used for producing low temperatures were the same in principle as were used by Dewar, Linde and Hampson, and indeed by Cailletet and Pictet. The obvious way to cool a substance is to place it in thermal contact with a substance colder than itself Any substance will do, and it is clear that, in the first stages at any rate, a gas will be the easiest to cool , for to reduce the temperature we must slow up the motion of the molecules. There are two simple

ways of doing this. The first is to let them collide with particles moving away from them. If a gas molecule is reflected from a fixed surface at the same temperature as the gas, its velocity on the average will be as great after the collision as before. But if the surface is not fixed but receding, the effective relative speed at the moment of collision will be reduced. Hence if gas molecules, instead of being enclosed in a vessel with fixed walls, are reflected from, say, a receding piston, their velocity will be lowered and the temperature of the gas will fall This is what happens when the temperature is reduced by the conversion of heat into external work The second method to cool a gas is to allow it to expand, that is, allow the molecules to recede from one another. If they naturally attract one another appreciably, this mutual attraction will tend to reduce their speed as they move apart, in other words, to reduce the temperature. This is the so-called Joule-Thomson effect which has been largely used in liquefying gases

A liquid gas produced by either of these methods, or a combination of the two, can be further cooled by pumping off the gas above the liquid. This causes more molecules to escape than return, and thus by doing work against the mutual attraction, as in the Joule-Thomson effect, tends to cool the liquid. A limit is set to this method of cooling, of course, by the fact that the vapour pressure diminishes exponentially with falling temperature. When the number of molecules which evaporate in unit time is so small that their latent heat just balances the inflow of heat due to imperfect insulation, no further reduction of temperature can be achieved By these means, using liquid helium and a battery of the most efficient pumps obtainable, a temperature of 0 7° was reached at Leyden by Keesom.

A totally different method, however, originally suggested by Debye and Giauque, has brought quite a new temperature region within our reach The entropy of a substance is a measure of its state of disorder. A set of molecules at rest in an accurate space-lattice would be in a state of complete order, that is, their entropy would be zero. As soon as their positions or motions vary, the entropy increases. Now paramagnetic salts contain atoms which behave like small magnets. Obviously, if their axes are all aligned parallel to one another, their positional state of order will be greater than when they are oriented at random. If we apply an external magnetic field, the axes of the magnetic atoms will all set themselves parallel to the lines of force. The entropy due to their positional disorder will therefore decrease; hence if the substance is thermally insulated, the entropy due to their thermal motion must increase; in other words, heat will be developed. Now if this heat is carried away, for example, by placing the substance in contact with liquid helium, and the substance is again thermally insulated, it is clear that one can cool the substance by reversing the process. For when the external field is removed the axes of the atomic magnets will tend, under the influence of thermal agitation, to resume their natural disordered condition, the positional entropy will increase at the expense of the entropy of agitation and the temperature must fall.

This effect was utilised by Giauque in California and by de Haas and Wiersma in Leyden in 1933 and by Kürti and Simon in Oxford in 1934 to cool substances to extremely low temperatures. Experiments in the region between 0·03° and 1° can be carried out without difficulty, and at Leyden, where a very strong magnet is available, a temperature of 0 005° has actually been reached. A great deal of work will have to be done before this method is fully exploited, as for each temperature range a suitable paramagnetic salt is required, but there is little doubt that by employing it in cascade or otherwise, extremely low temperatures will be as readily accessible to research as were temperatures a thousand times higher twenty-five years ago

The measurement of these low temperatures naturally presents quite a new set of problems. Down to 1°, of course an ordinary helium gas thermometer can be used, further, since all its constants are known, one can calculate the vapour pressure of helium and utilise this as a measure of the temperature down to 0 7° or even 0 5°. But at 0·1° the vapour pressure of helium is 10^-[illegible] mm. and at 0·03° it is 10^-[illegible] mm. of mercury. Quite different methods must therefore be employed to measure such temperatures

Fortunately, one such method is ready to hand. The magnetic susceptibility of a paramagnetic salt is a measure of the ease with which the magnetic atoms can be oriented. The smaller the thermal agitation the more readily will they be directed by an external field. Thus, roughly speaking, the susceptibility will be inversely proportional to the temperature Obviously this rule is no more than a first approximation. Accurate thermometry will only be possible when the susceptibility curve has been linked up to the gas thermometer curve by means of proper thermodynamic cycles, a research now in hand at Oxford. Once this has been done, these susceptibility measurements will form a very convenient form of thermometry enabling an accuracy of 10^{-4} degrees or even better to be achieved.

Most of the phenomena at low temperatures have fallen into line with the predictions or at any rate the explanations of the quantum

dynamics. The atomic heats of simple substances agree as well as can be expected with the theoretical expressions, especially when one remembers the difficulty of working out and weighting all the modes of oscillation of a space-lattice of atoms or even complicated molecules. The atomic frequencies calculated from elastic constants agree with those derived from the atomic heat curves; even the fine structure in the spectral lines due to nuclear spin is mirrored in anomalies in the specific heats at the calculated temperatures Quantum considerations, as Simon showed, enable one to understand the curious fact that helium remains liquid, in the sense that it has a very low viscosity, down to the lowest temperatures, though there is a point at which a certain order tends to be established. For with liquid helium the zero point energy is so great that at atmospheric pressure the substance can never become solid. If the pressure is raised, it can be reduced to the crystalline state even at temperatures ten times as high as its boiling point.

There is, however, one phenomenon, and that a very striking one, that has so far defied adequate explanation. In 1913 Kamerlingh Onnes announced that when mercury was cooled below 4° its electrical resistance vanished Supra-conductivity, as this effect is called, was afterwards found to occur in lead, tin and a number of other metals, though not by any means in all, for example, not in copper as low as 0·05°. Even some semi-conductors exhibit the same property, such as niobium carbide—indeed in this substance supra-conduction sets in at the highest temperature so far observed, namely, 12°. All attempts to observe some trace of electrical resistance in the supra-conducting state have failed. A current induced in a ring of supra-conducting material continues to run with undiminished strength for days on end. The phenomenon does not seem susceptible of explanation by any of the ordinary theories of electron conduction

Much work has been done in Leyden, Berlin, Toronto and Oxford on this strange effect, and the somewhat complicated phenomena are gradually being disentangled But whether it will be possible to fit it into the general scheme or whether it may not require some new mode of approach it is too early yet to say.

Though more low temperature research has been carried out in the last twenty-five years than in all preceding periods put together, and though temperatures within one hundredth of a degree from the absolute zero have been attained, there is no question of our having reached finality

Our nearness to the absolute zero is apparent rather than real; if we had chosen to measure the temperature on a geometric rather than an arithmetic scale, it would have been less convenient in many ways; but it would have made it clear that, towards low temperatures, as towards high, there is always an infinite distance ahead of us, and in each such range we may expect new effects and new phenomena.

Fortunately, there are within the Empire laboratories where these effects can be studied. At Oxford, Cambridge and Toronto, work at liquid helium temperatures and below is being done It may be hoped that the next generation will see the position of pre-eminence enjoyed by England in Dewar's time recaptured, and that advances as valuable and important as those which have signalised the past quarter of a century await us in the next.

Cosmic Rays

By DR. ARTHUR H. COMPTON, University of Chicago, and George Eastman Visiting Professor in the University of Oxford

THE twenty-five year period of King George's reign includes almost the entire history of the study of cosmic rays. The presence of these rays was revealed by a series of experiments carried on between 1909 and 1914. Wulf, on the Eiffel Tower, and Gockel, flying in a balloon to 4,500 metres, found that rays from radioactive sources in the ground could not account for the ionisation observed at high altitudes, and suspected some radioactive material in the upper atmosphere[1]. Hess, in a series of notable balloon flights, found an actual increase of ionisation with increasing altitude, and concluded "that a radiation of very high penetrating power enters our atmosphere from above". These experiments were at first criticised by other investigators, but were quickly confirmed by the more precise observations of Kolhörster, and have since been found correct in all their essentials.

After eleven quiescent years, Millikan made some bold speculations regarding the origin of these penetrating rays, which showed in a striking manner that their study might well give important new information regarding the evolution of the universe. Largely through his experiments and those of Hoffmann, the existence of the radiation

was by this time generally recognised, and an intensive series of investigations was started by many physicists throughout the world It was found that the rays which Hess had discovered are of a far more penetrating kind than any known before, being perceptible to a depth of hundreds of feet below the ground They bring into the earth a total amount of heat somewhat smaller than that of starlight; but the energy of the individual cosmic ray is thousands of times greater than the most powerful artificial ray that man has produced The more recent studies have sought to learn the nature of these rays, where they come from, how they are produced, and what effects they have on objects which they strike

NATURE OF THE COSMIC RAYS

It was at first natural to suppose that these highly penetrating rays were of the same nature as the γ-rays from radium, the most penetrating rays then known Though this view has not been entirely abandoned, the large majority of investigators now believe them to be electrically charged particles This view of their nature was first urged by Bothe and Kolhörster, who found associated with the cosmic rays some electrical particles which were as penetrating as the cosmic rays themselves They noted further that if such electrical particles approach the earth from all directions, some of those near the equator should be so deflected by the earth's magnetic field that the intensity of the rays should be less there than near the poles Through the experiments of Clay and many others, the existence of such a 'latitude effect', which depends upon the earth's magnetic field just as the theory predicts, has at last been established This has proved the existence of an important component of the cosmic rays which is electrically charged

More recently, using methods developed by Piccard, Regener and others, it has been possible to extend the measurements of cosmic rays high into the stratosphere Typical data taken at different latitudes are shown in Fig. 1. Here it will be noted that the latitude effect, which is only 15–20 per cent at sea-level, has become a factor of 40 near the top of the atmosphere. That is, nearly all the incoming rays are affected by the earth's magnetic field, and are hence electrically charged. Even of the small percentage which penetrates the magnetic barrier at the equator, supplementary experiments show that a large fraction and perhaps all is electrical in character[2,3].

A method of analysing the various electrical components has recently been developed[2,3], in which the earth is used as a huge natural mass-spectrograph, similar in principle to the laboratory instrument for identifying the isotopes of elements. The earth's magnetic field permits only those particles to reach the earth which have an energy, and hence a range in air, greater than a certain minimum This minimum range is different for every type of particle. Analysis of such curves as those shown in Fig 1 has enabled us to distinguish three groups of rays having distinct range minima Best agreement between these observed minimum ranges and those calculated from the earth's magnetic field is found if the least penetrating group of rays is identified as α-particles, that of medium penetration as electrons (positive or negative), and the most penetrating ones as protons

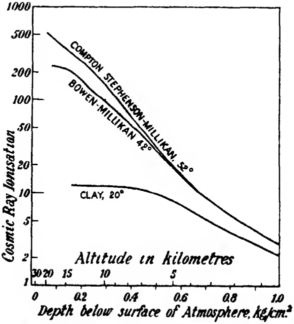

FIG 1 Cosmic ray ionisation at different altitudes as observed at different geomagnetic latitudes, showing great latitude effect at high altitudes

It is possible that this analysis may require revision as the result of further measurements, the method, however, seems adequate to supply a definite identification of the components of cosmic rays as soon as sufficiently precise data are available In the meantime, other observations, especially the directional experiments of Johnson, Alvarez, Rossi, Clay and others, lend support to this tentative analysis[4]. Rapid progress is thus being made toward a complete determination of the composition of cosmic rays.

WHENCE COME THE COSMIC RAYS ?

One of the most significant aspects of the latitude effect is its implication that the cosmic rays originate far beyond the earth's atmosphere. The earth's magnetic field is not strong enough to bend appreciably any radiation produced within the atmosphere before it is stopped by collisions with

molecules Furthermore, the cosmic ray intensity is found to depend upon the average magnetic effect of the whole earth, and to be almost unaffected by 'local' magnetic idiosyncrasies which may extend even over a whole continent This must mean that they feel the effect of the earth's magnetism when yet thousands of miles from the earth's surface.

Except for deflection by the earth's magnetic field, however, the cosmic rays are found to approach the earth nearly uniformly from all directions. Outside the earth's atmosphere, we fail to find any isotropic distribution of matter within our galaxy where such rays might originate The extra-galactic nebulæ or space itself would, on the other hand, satisfy the condition of spherical symmetry Calculations by both Eddington and Lemaître have shown that the probable absorption of a cosmic ray traversing the matter in interstellar space with about the speed of light for 10^{10} years would be wholly negligible If, however, these rays are subject to the same red shift as that which occurs in the light from the distant nebulæ, the rays originating at distances as great as 10^{10} light years would arrive at the earth with only a small fraction of their initial energy If the rays are being continuously produced, therefore, their isotropic distribution suggests that most of them originate in the remote galaxies or in remote space, at an effective distance of between 10^9 and 10^{10} light years An alternative would be to suppose with Lemaître that they were formed at the beginning of the expansion of the universe, and have ever since been coursing through space

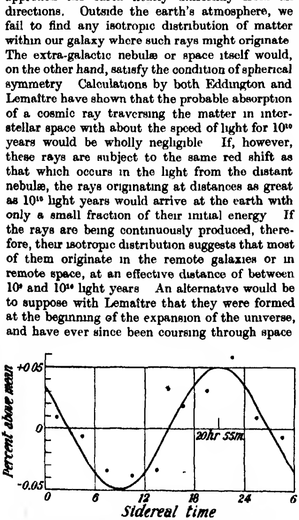

FIG. 2. Apparent effect due to rotation of galaxy Curve, theory; data,[4] complete year's observations by Hess and Steinmaurer

Some positive support for this view of the remote origin of cosmic rays is given by the fact that there appears to be an effect on their intensity due to the rotation of the galaxy[4]. According to Stromberg and Hubble, this rotation carries us toward declination 47° N. and right ascension 20 hr. 55 min., at a speed of about 300 km. per second—one thousandth the speed of light. If the source of the cosmic rays is outside our galaxy and at rest relative to its centre of gravity, calculation shows that at our latitude this motion should cause a diurnal variation, following sidereal time, through a range of the order of 0 1 per cent The best available records of cosmic ray intensity[4] show, as in Fig 2, a variation with sidereal time of about the predicted magnitude, and with its maximum at precisely the predicted time Though further experiments are necessary before other possible interpretations of this sidereal time variation are ruled out, the complete agreement with the predictions may justify the presumption that it is really due to the rotation of the galaxy This would necessarily imply that an important part of the rays originates outside the galaxy, a long-wanted justification of their rather heuristic appellation of 'cosmic'

How are the Rays Produced ?

Of the many hypotheses regarding the origin of cosmic rays, none has received sufficient experimental support to gain general acceptance Those which assume the primary cosmic rays to be photons appear to be in definite conflict with the observed latitude effect Also those which would ascribe their origin to transformations of atomic nuclei with resulting loss of mass are unable to account for the huge energies of from 10^9 to almost 10^{13} electron volts which the more recent studies[7] seem to require for the individual rays Local or interstellar electric fields have been suggested, but the maintenance of such fields in highly ionised stellar atmospheres seems an insurmountable difficulty There remain, however, a number of theories which cannot thus be excluded. Prominent among these are Lemaître's hypothesis of 'super-radioactive particles' emitted at the initial explosion of his expanding universe, Swann's theory of the acceleration of electrical particles by electromagnetic induction from the changing magnetic fields of 'sunspots' on giant stars, and Milne's view[8] that the particles owe their energy to the gravitational attraction of the universe At present we are unable to give these suggestions a definitive experimental test

Action of Cosmic Rays on Matter

One of the most fruitful lines of cosmic ray research has been the study of their effects on passing through matter. Especially valuable have been the experiments with Wilson chambers in strong magnetic fields, and the use of Geiger-Müller counting tubes These and other methods have shown that a complex mixture of secondary rays is excited by the primary cosmic particles In this complex mixture, Anderson made the remarkable discovery of positive electrons, or positrons, which have since been found to play

an important rôle in the absorption of high energy photons.

A prominent feature of the secondary radiation associated with cosmic rays is the occurrence of 'showers' of two to twenty or more high-speed particles emanating apparently from the same point These particles are about equally divided between positive and negative electrons. Furthermore, these showers themselves frequently occur in groups, all excited by some 'shower producing radiation'. This 'shower producing radiation', according to studies by Rossi, Blackett, Anderson and others, seems to consist of photons, similar to X-rays, produced at the collisions of the primary cosmic ray particles with atomic nuclei. Studies by Johnson[4] of the directional asymmetry of the shower producing radiation suggest that it is excited chiefly by the electron component of the primary cosmic rays, and that this component consists of about equal parts of positive and negative electrons.

Contrary to the situation for rays from radioactive materials, it would seem that, for these very high energies, photons may be more absorbable than electrons of the same energy, and that protons are probably the most penetrating of all The theories of Oppenheimer and Bethe and Heitler indicate that electrons are stopped chiefly by the excitation of photon radiation (X-rays). This results in an almost exponential type of absorption, similar to that of photons. These unanticipated results account in part for the confusion in our early attempts to identify the nature of the primary rays. The experimental study of these energy losses is beginning to give valuable results[9], while their adequate theoretical treatment seems to require a further extension of quantum-relativity electrodynamics. It seems probable that studies of these energy losses may supply our best means of testing those extensions of the present electrodynamics which are designed to account for the structure of electrons and nuclei.

Our analysis of the composition of cosmic rays is thus well under way, and from present indications should soon give conclusive results. The 'cosmic' origin of the rays, though perhaps not established, appears now more probable than ever How they originate is still obscure, but increased knowledge of their characteristics has helped to limit the types of hypotheses that are admissible Of immediate value is the use of these rays as a tool They have made possible the discovery of the positron, and now afford a means of extending our studies of the properties of matter to energies a thousandfold greater than are available from any other known source.

[1] Detailed reviews of cosmic ray research, with comprehensive bibliographies, have recently been published by A. Corlin (*Annals of the University of Lund*, No 4; 1934) and E. Steinke (*Ergeb exakt. Naturwiss*, 13, 89, 1934) I shall here give references only to some of the very recent work not discussed by these authors

Progress in Knowledge of the Upper Air

By DR. F J. W. WHIPPLE, Superintendent of the Kew Observatory, Richmond, Surrey

IN considering progress in knowledge of the upper air during the past twenty-five years, the first point to notice is that it is roughly true that in 1910 there was little more to be learned about the condition of the atmosphere below 20 km. and a great deal to be learned about the atmosphere above that level.

THE STRATOSPHERE

The most striking discovery that has ever been made in meteorology, the discovery that the familiar decrease of temperature with increasing height comes to a sudden stop at some 10 km. above sea-level, was already well established by 1910. The discovery was announced in 1899 by Teisserenc de Bort, who afterwards coined the names stratosphere for the isothermal layer and troposphere for the lower part of the atmosphere. A name for the transition, the tropopause, was introduced by Sir Napier Shaw comparatively recently. De Bort reported in 1902 that the tropopause was higher in anticyclones than in cyclones, the variation being from 12·5 km. to 10 km. In 1908 it was discovered by a German expedition to Victoria Nyanza that the tropopause was at a height of nearly 17 km. and that the temperature was about 190° A., much lower than the average temperature, 216° A., recorded in Europe.

It was soon realised that the explanation of the existence of the stratosphere must be based on the study of radiation. The permanent gases of the atmosphere are almost perfectly transparent to radiation both in the visible spectrum and in the part of the infra-red in which objects at atmospheric temperatures radiate. On the other hand, water vapour absorbs and radiates in this part

of the infra-red. The theory put forward by Gold in 1909 depended on the investigation of the balance of radiation absorbed and given out by water vapour. The theory remains incomplete, for it is not clearly understood why there should be a sharp transition in the temperature gradient at the tropopause, and the contrast between the conditions over the equator and in higher latitudes has not been explained.
